Observational X-ray Astronomy

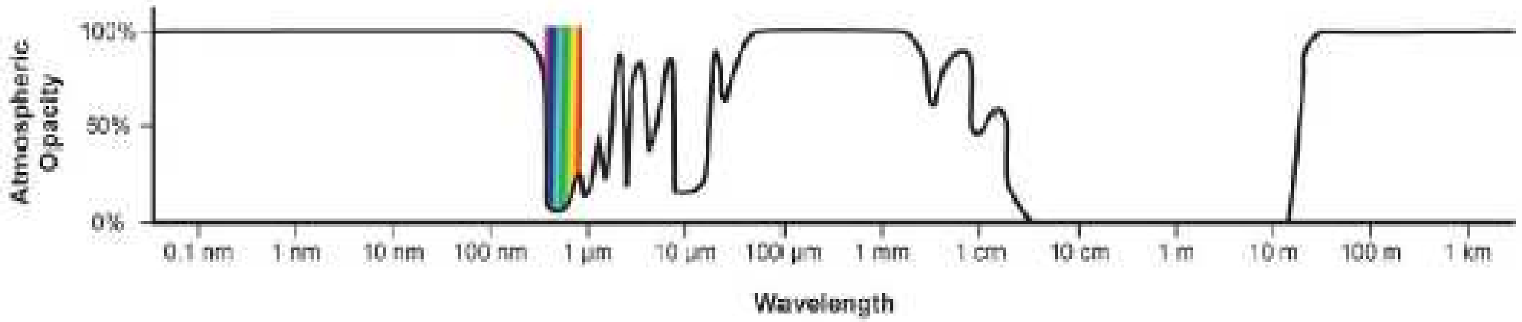
David Buckley
SALT

Topics covered:

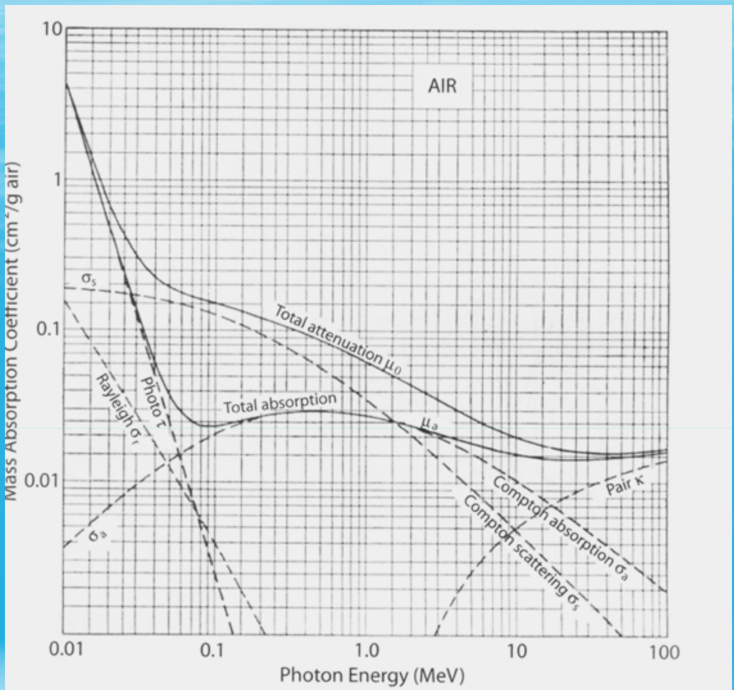
- X-ray astronomy history
- X-ray radiative processes
- X-ray detection
- X-ray missions
- X-ray instruments

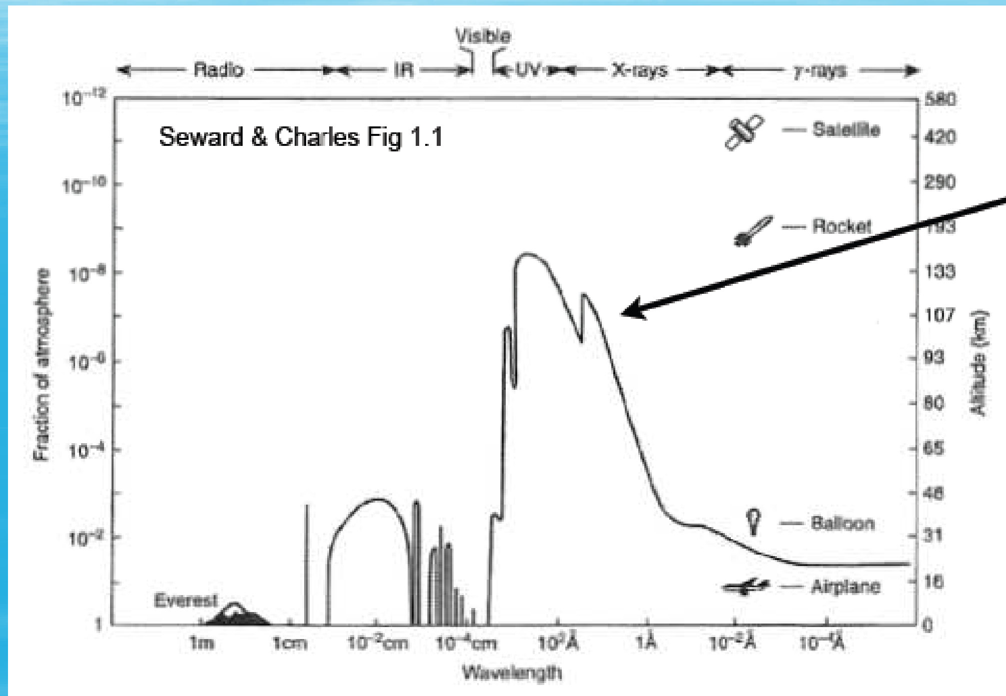
X-ray astronomy

- At very short wavelengths we deal with photon energies instead of λ
  - Measured in electron Volts, eV
- X-rays: energies of approx 100eV to 100keV
  - Absorbed by the atmosphere so observatories are space based



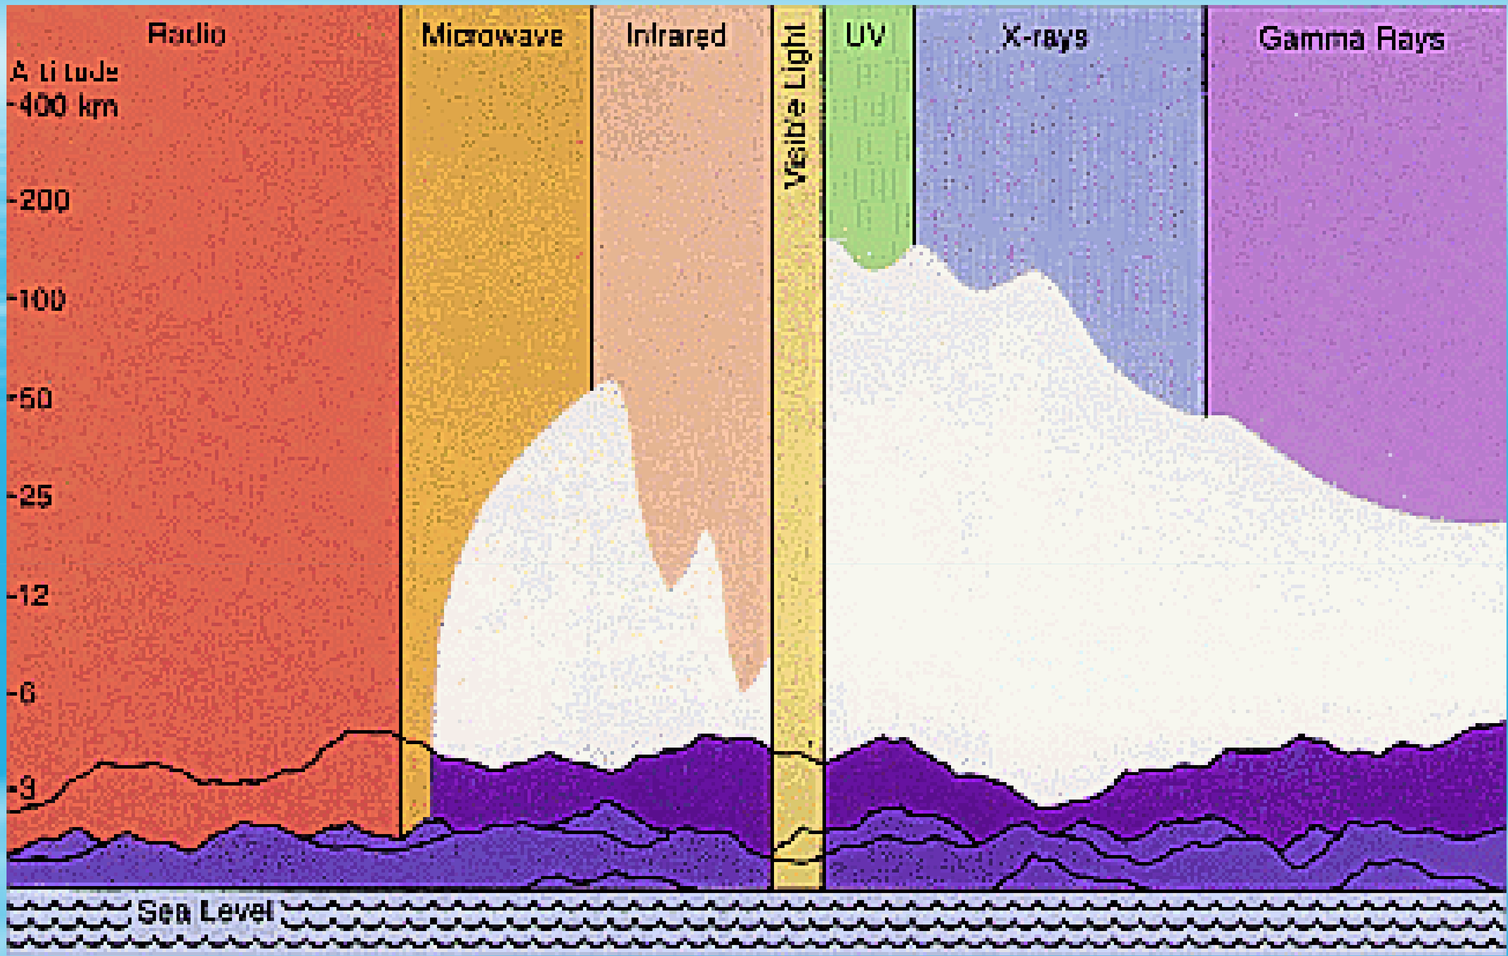
X-ray Absorption in the Atmosphere





- Photoelectric absorption, Compton effect, pair production
- Height for 50% of attenuation changes with E
- 10 cm of air stops 90% of 3 keV photons

Attenuation

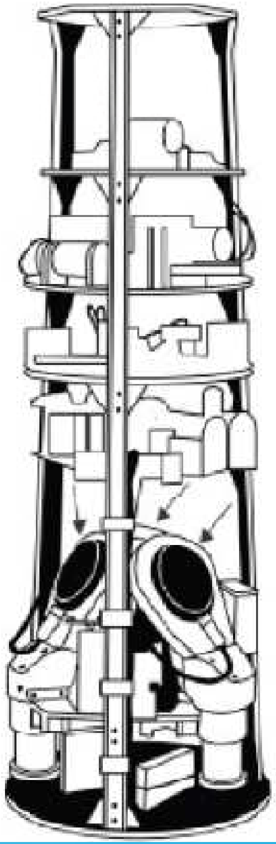


- **Early experiments were done with balloons & rockets**

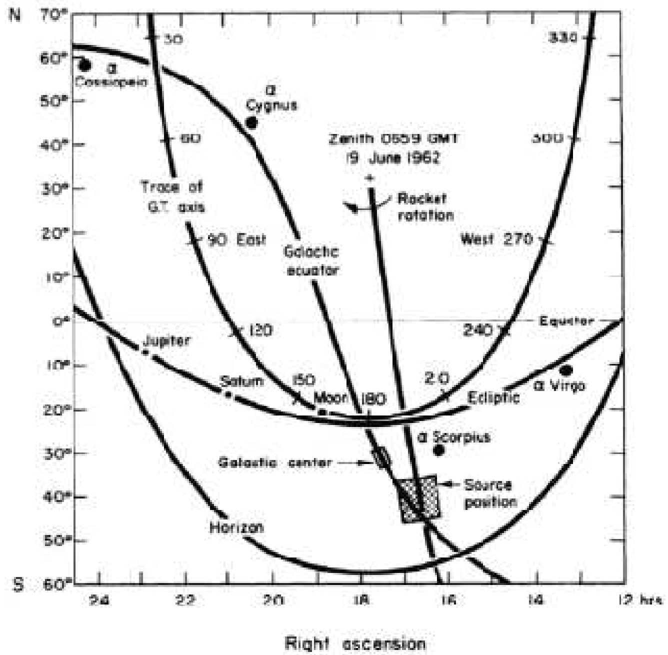
Pioneering Rocket Observations

Nobel prize 2002: Riccardo Giacconni

"for pioneering contributions to astrophysics, which have led to the discovery of cosmic X-ray sources"

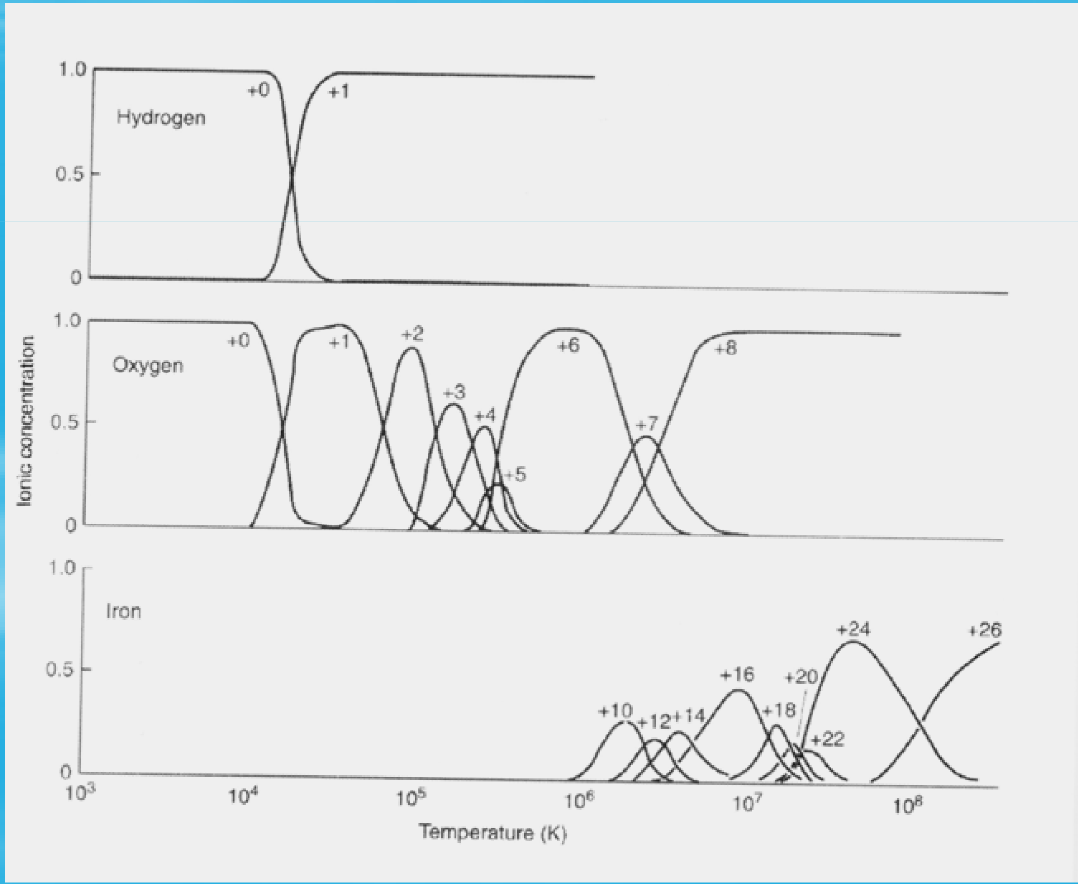


1962: experiment to search for X-rays from the lunar surface: three Geiger counters on a Aerobee rocket



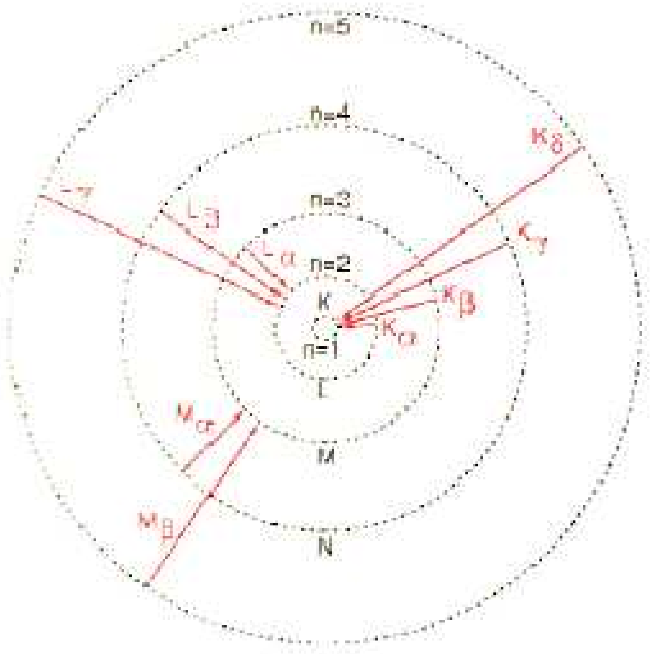
Ionization

- Ionization temperature (Boltzmann)
- High degrees of ionization require high temp/energy
- Equivalent to high photon energies (X-rays)
- Line emission from electronic transitions



Ionization

- For high Z atoms, K shell electrons require X-ray energies for ionization

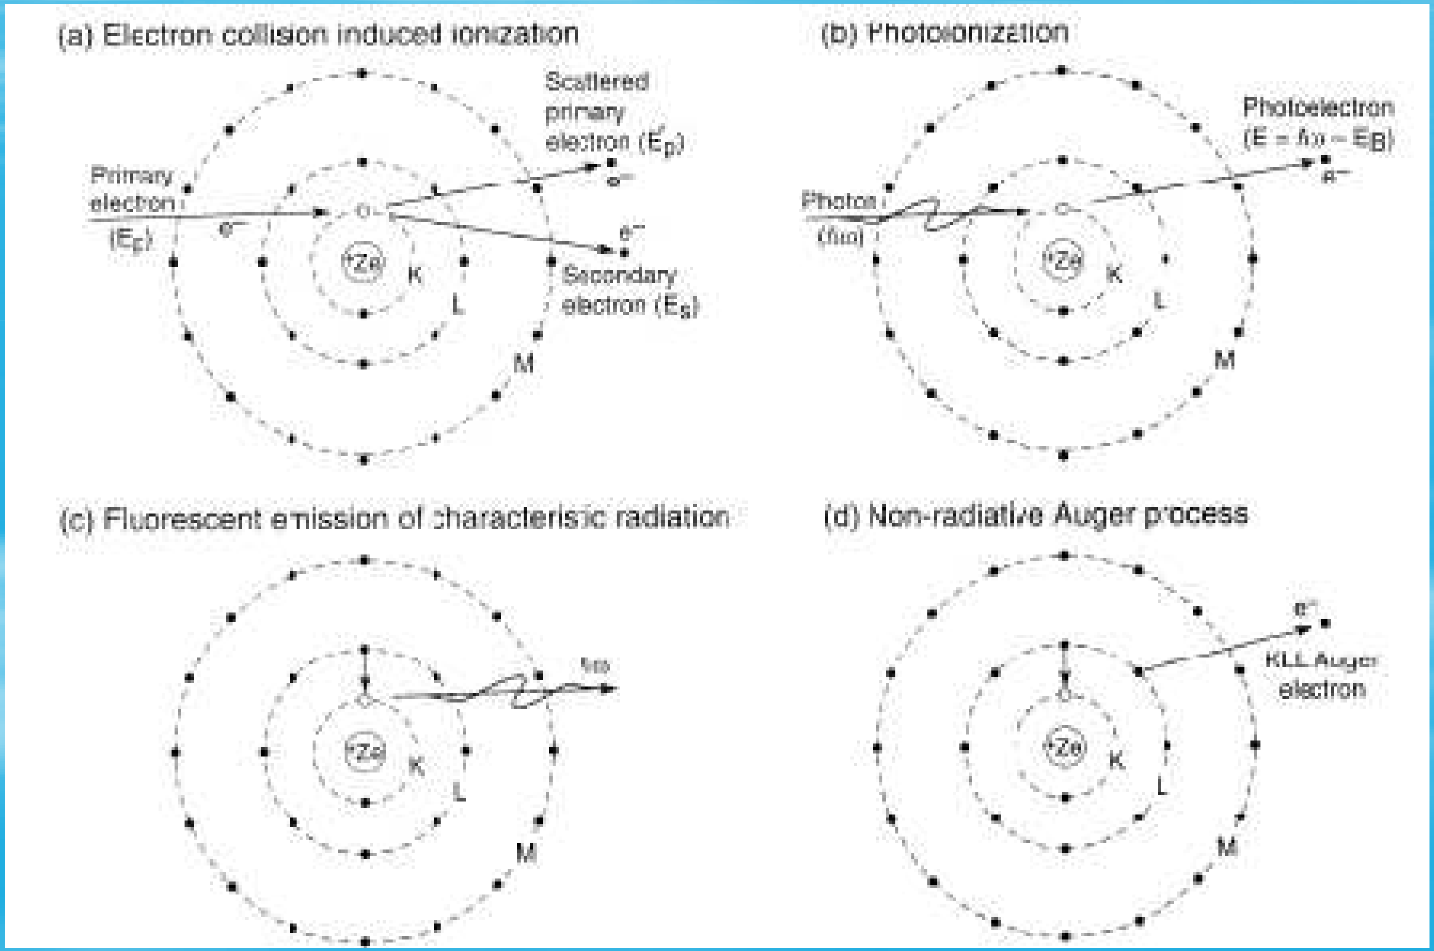


Inner-shell ionization: $\gamma, e^- + I \rightarrow I^{*+} + 2e^- \rightarrow I^+ + e^-, \gamma$

Important 6.4 keV line from Fe I - Fe XVI

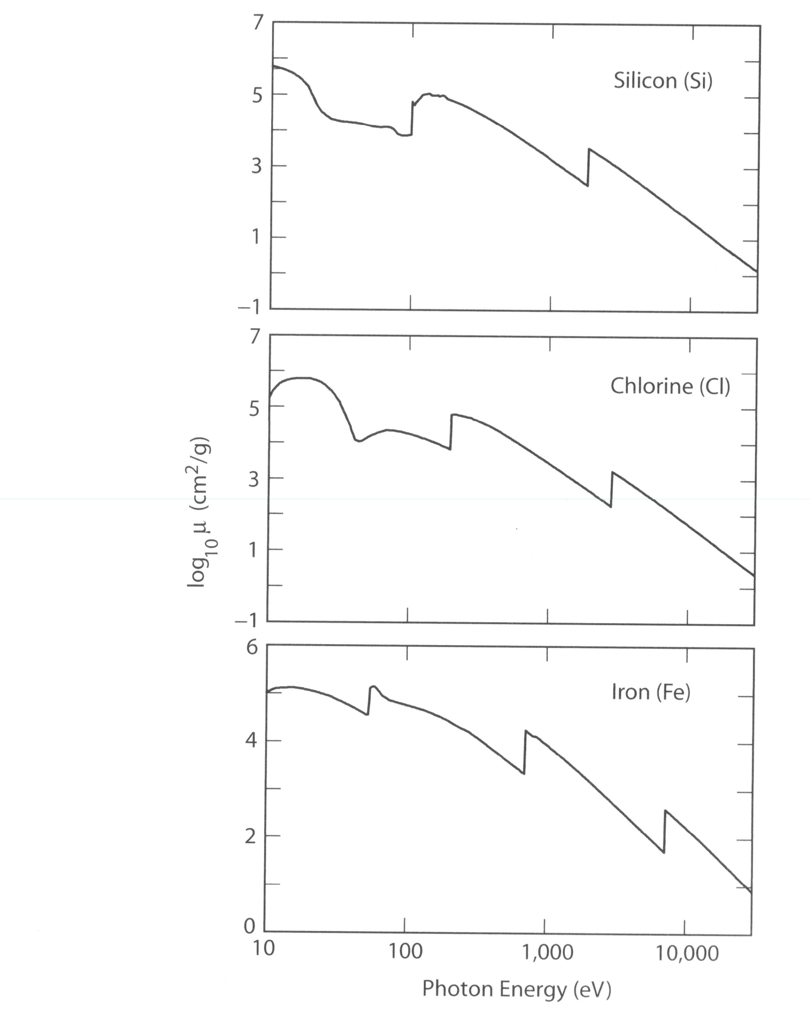
Ionization

- Basic ionization and emission processes in atoms



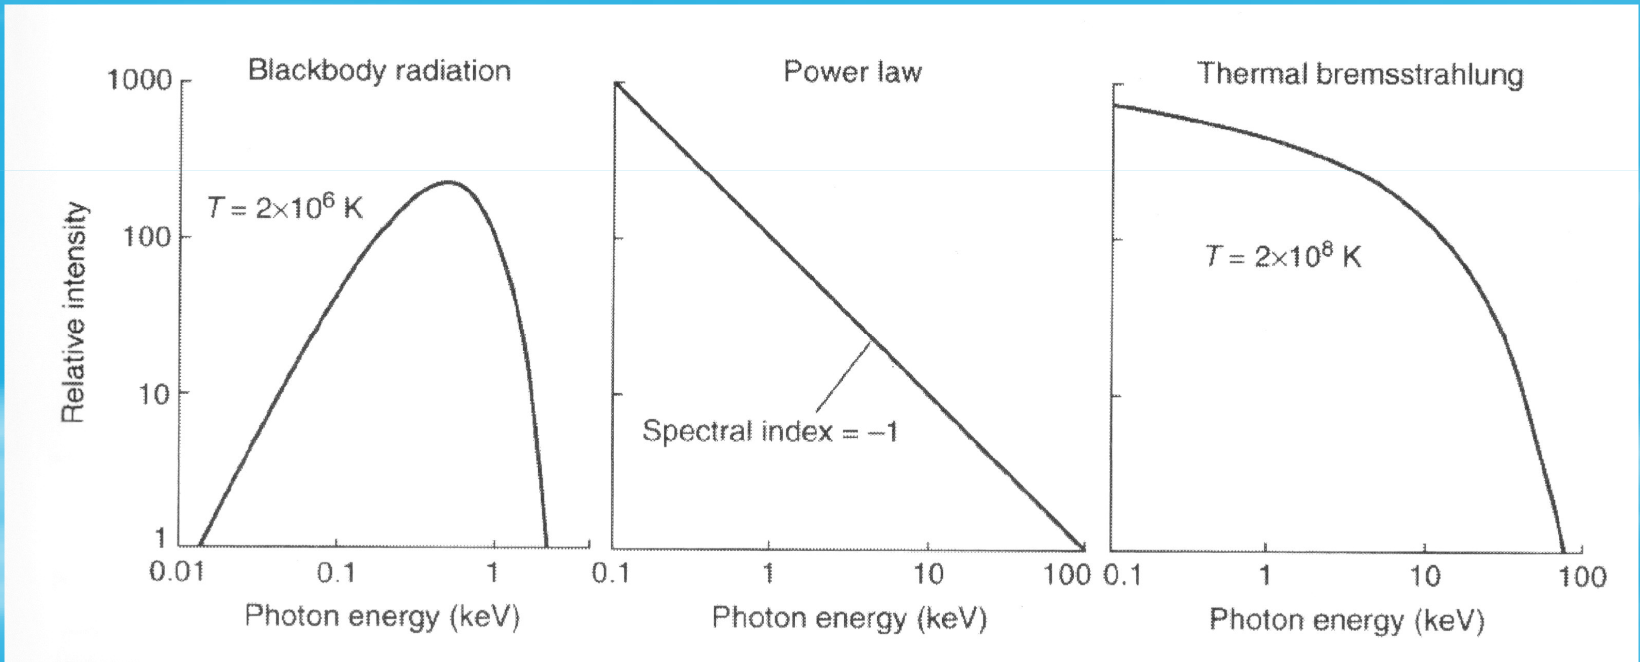
Ionization: Spectra

- Absorption “edges” from K, L, M shells



X-ray Emission Processes: Spectra

- Blackbody emission
- Power Law emission (synchrotron processes)
- Thermal bremsstrahlung (free-free emission)



X-ray Emission Processes: Spectra

energy range:
0.1- 100 keV (0.12-120 Å)
(hard X-rays up to 500 keV)

continuum

bremsstrahlung
blackbody
synchrotron
(inverse) Compton scattering
radiative recombination

lines

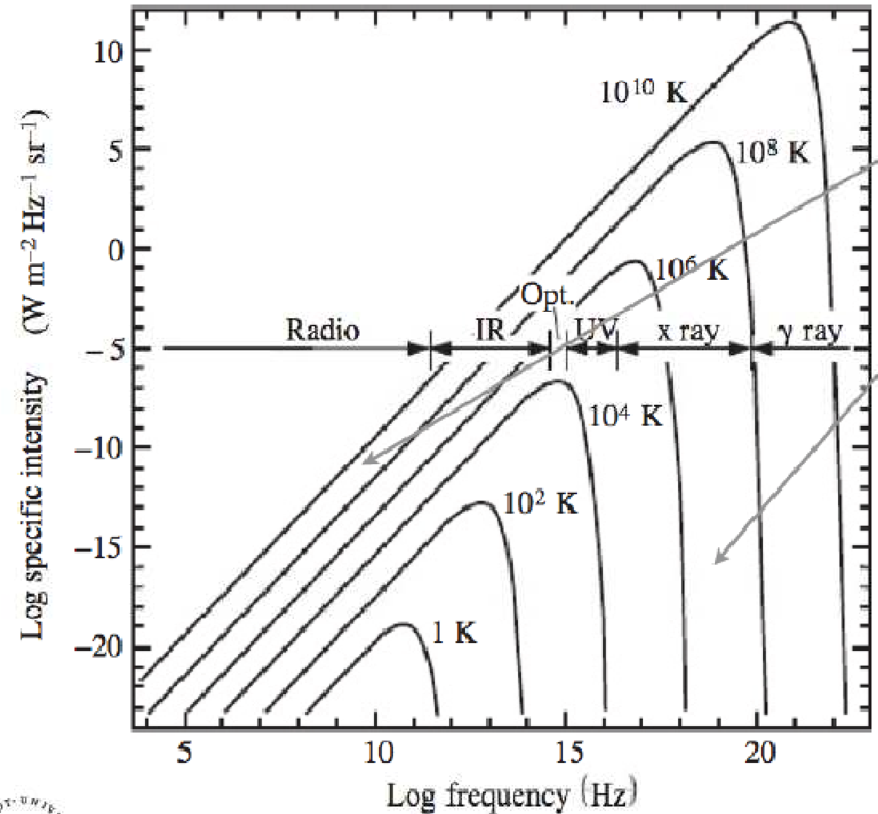
charges exchange
fluorescence
thermal

X-ray band includes K-shell transitions (n=2 to 1) for all elements heavier then He

Black Body Emission

- The Planck function

Plank radiation law $$I(\nu,T) = \frac{2h\nu^3}{c^2}\frac{1}{\exp^{h\nu/kT} - 1}$$



Rayleigh Jeans approximation

$$I(\nu,T) \approx \frac{2\nu^2}{c^2}k_BT$$

Wien approximation

$$I(\nu,T) \approx \frac{2h\nu^3}{c^2}\exp^{-h\nu/kT}$$

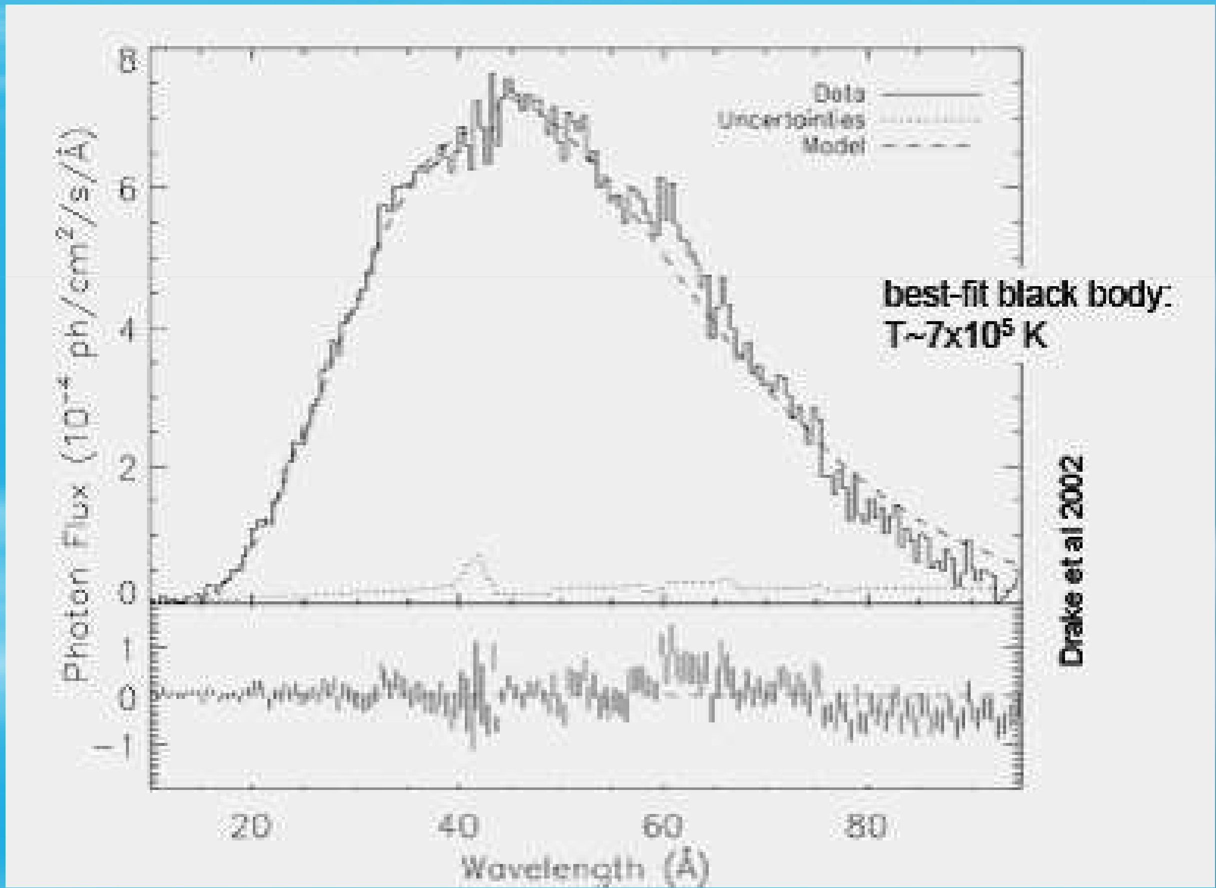
total energy flux

$$F = \sigma T^4$$

Star temperatures:
red dwarf: 2500 K
O star: 40 000 K
Newly formed neutron star: 10^6 K (?)

Black Body Emission

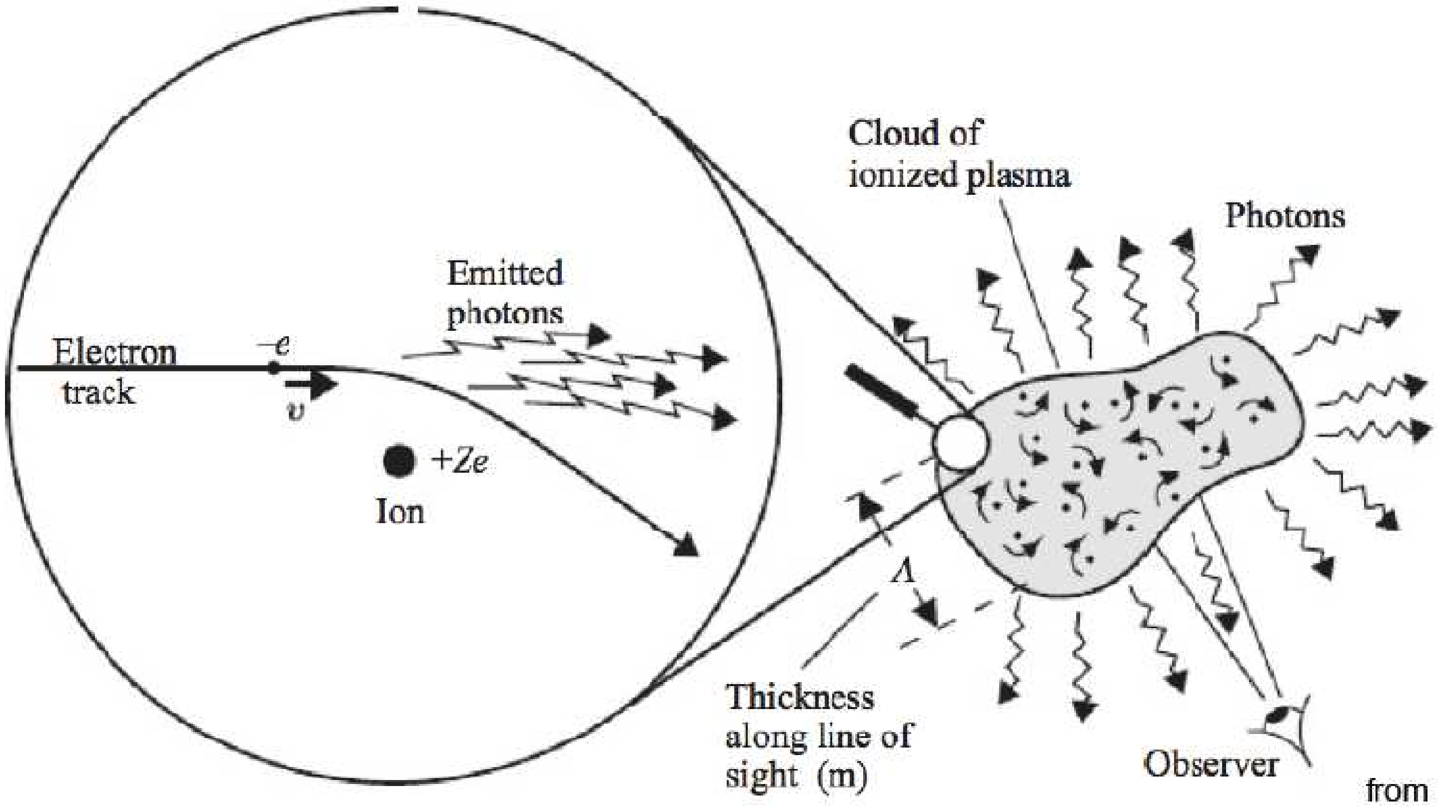
- Example of a hot black body: isolated neutron star at 700,000K
- Accreting from the Interstellar Medium (ISM)



Thermal Bremsstrahlung Emission

consider a hot optically thin plasma transparent to its own radiation in thermal equilibrium

Thermal Bremsstrahlung by electrons (Maxwellian velocity distribution)

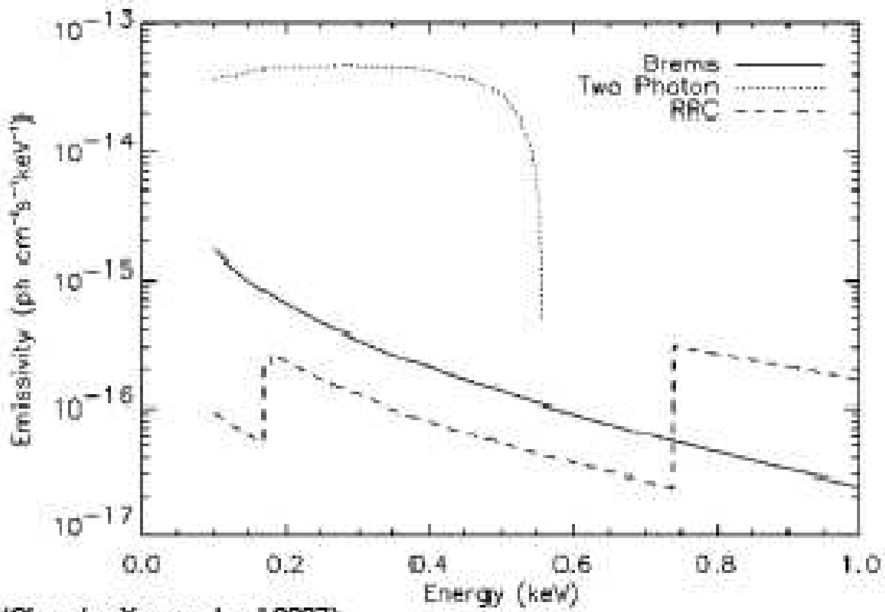


from Bradt 2008

Radiative Recombination
(free-bound transition)

capture of an unbound electron into a bound level i
radiated photon has energy E > E_I

$$X^+ + e^-(\epsilon) \rightarrow X^* + h\nu.$$



Smith (Chandra X-ray school 2007)

Sample
O VII
(collisional)
continuum

radiated energy:
$\sim N_e N(Z,I+1) E_I^{-3}$

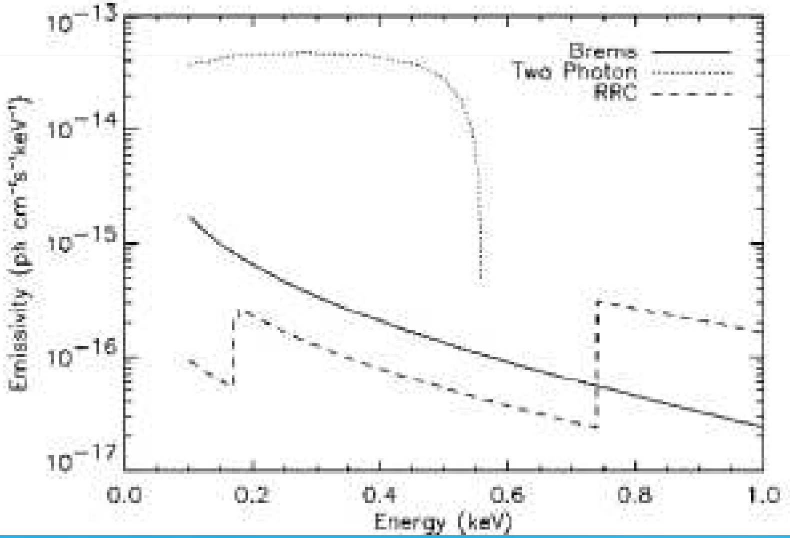
Two Photon Emission

(bound – bound forbidden transition)

a single electron transition accompanied by the emission of a photon pair
(in case the single photon transition is forbidden)

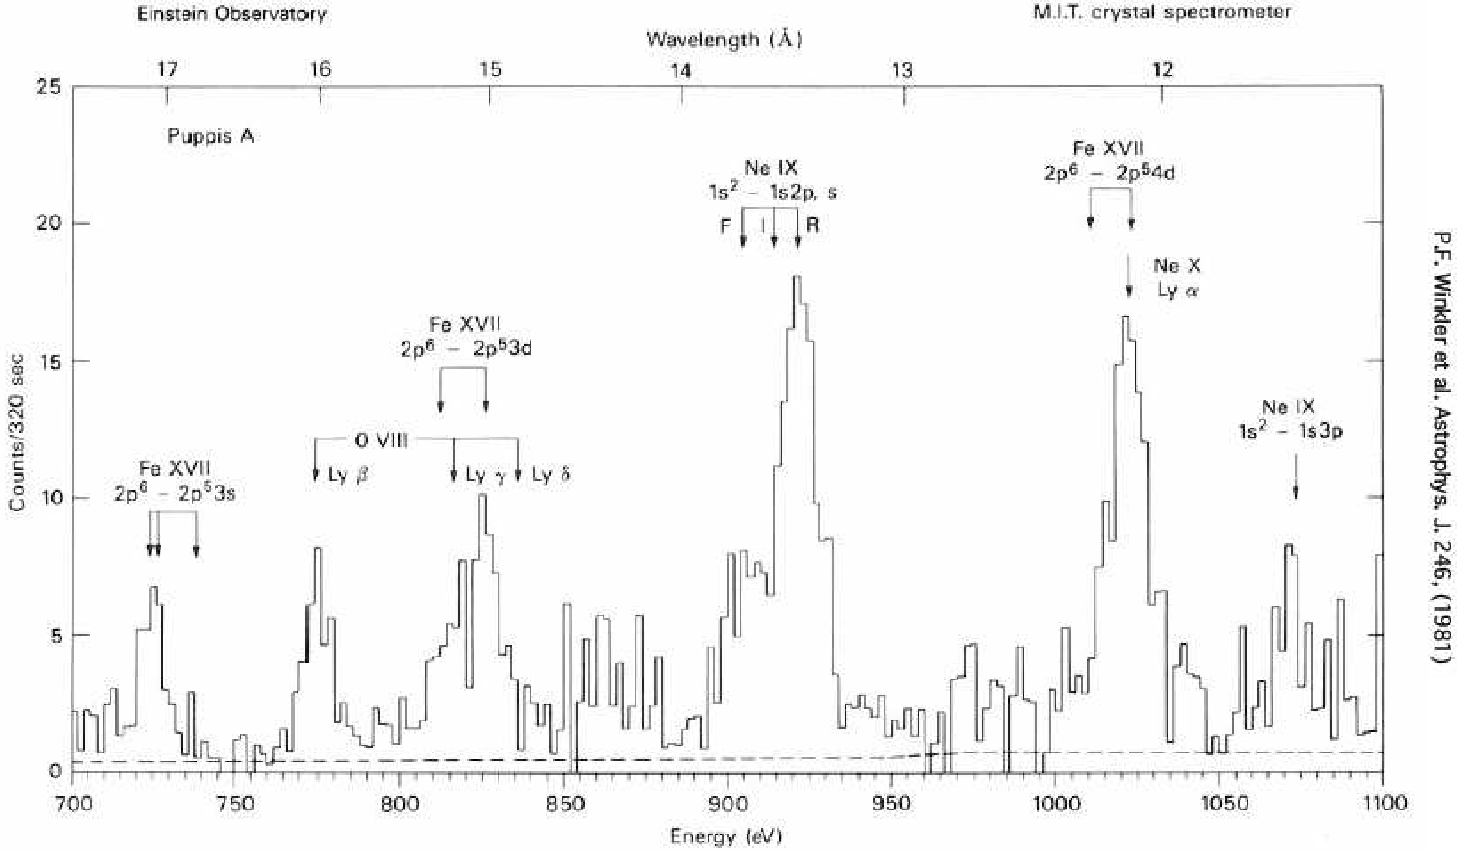
'forbidden' might be <<1/s (O VII: 1044/s):

O VII two-photon transition : $1s2s\ ^1S_0 \rightarrow 1s^2\ ^1S_0$



Sample
O VII
(collisional)
continuum

X-ray Line Emission



Temperature: Bremsstrahlung cut off and/or presence of lines
Composition: strength and energies of lines

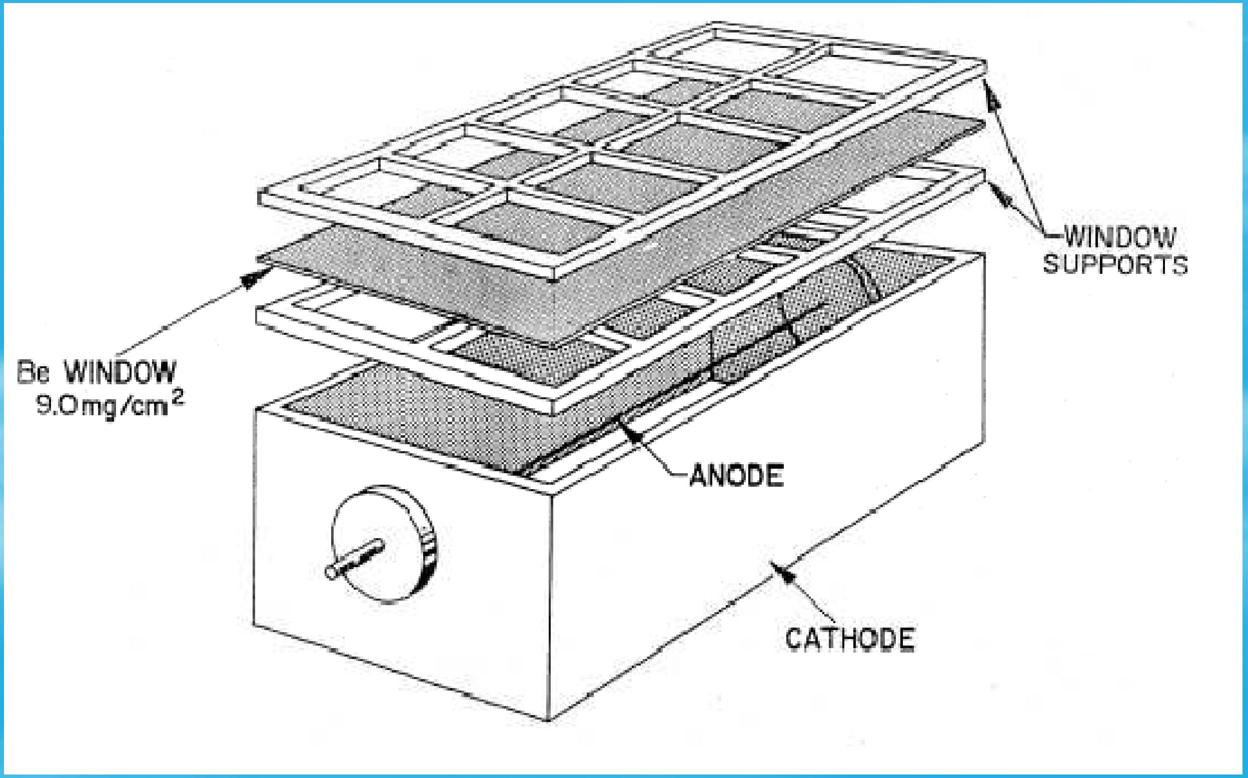
The First X-ray Astronomy Satellites

first survey at 2-20 keV
proportional counters

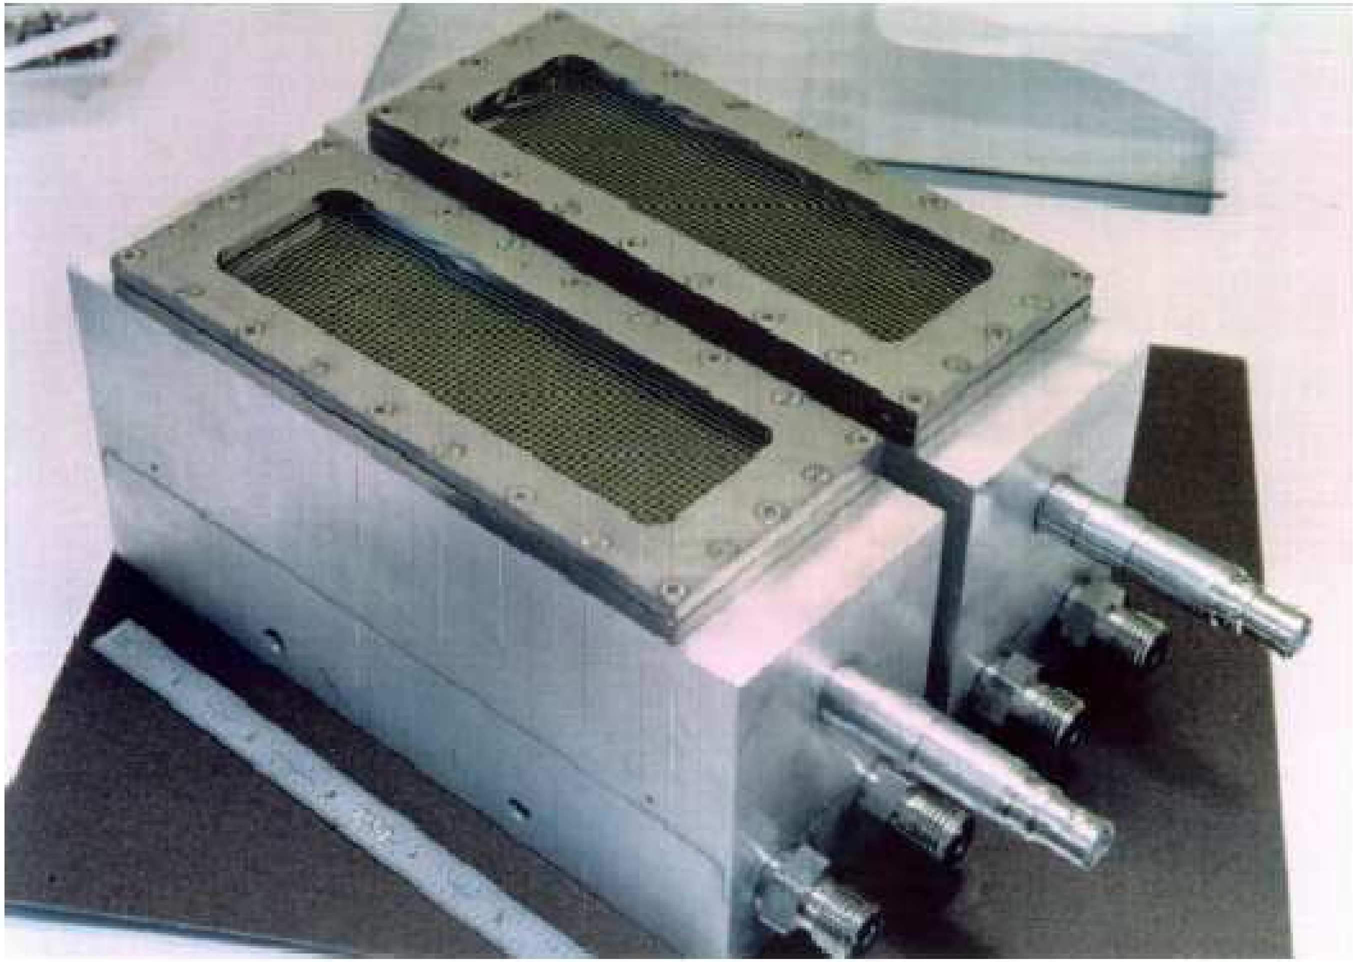
#1: Uhuru 1970 (NASA)

X-ray Detection

- First detectors were proportional counters
- Based of photoionization of a Nobel gas (e.g. Ar)
- Gain of $10^3 – 10^5$
- Single photon event are detected (need to be!)

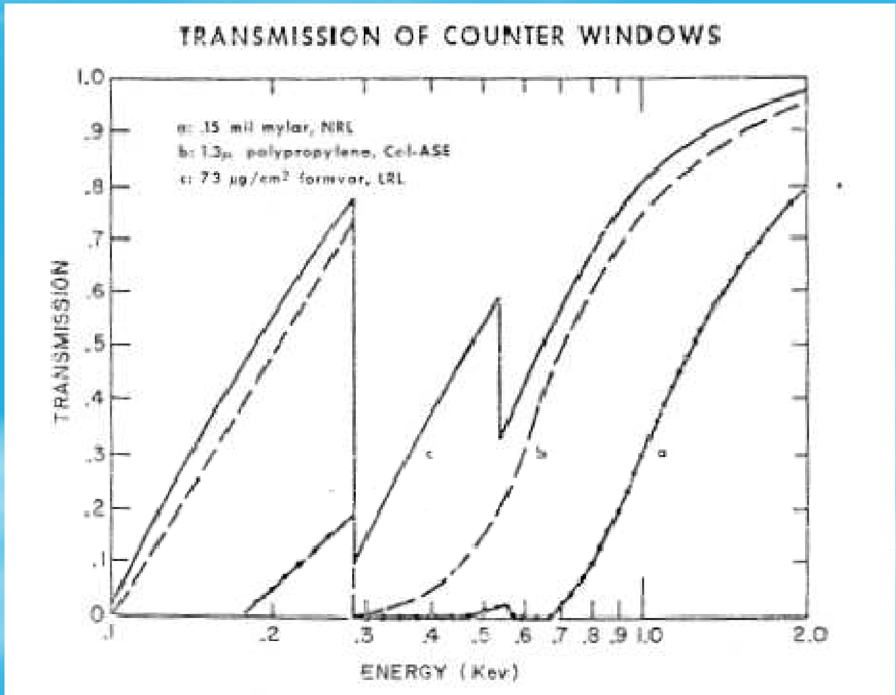


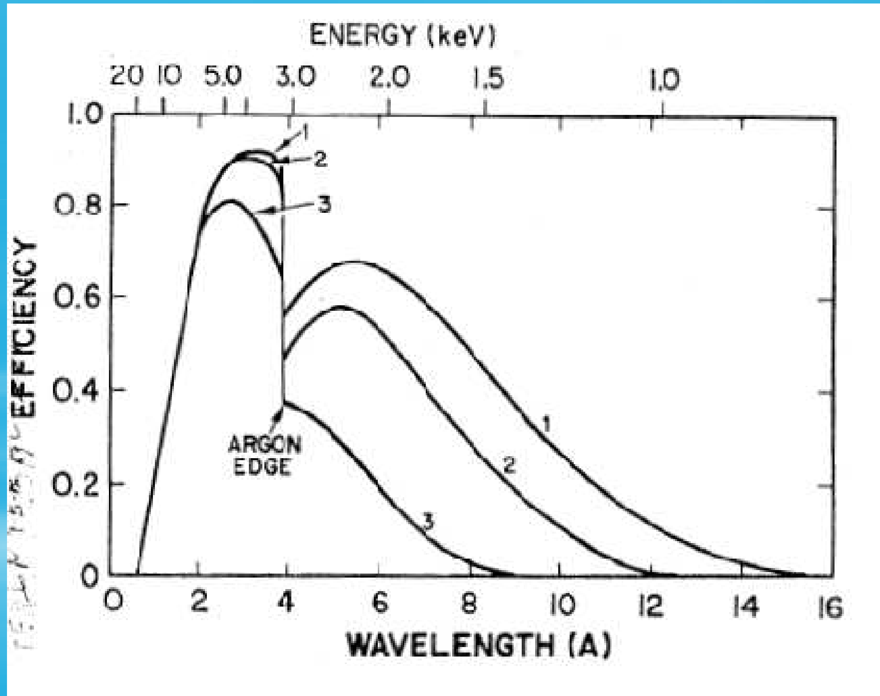
Proportional Counter



Proportional Counters

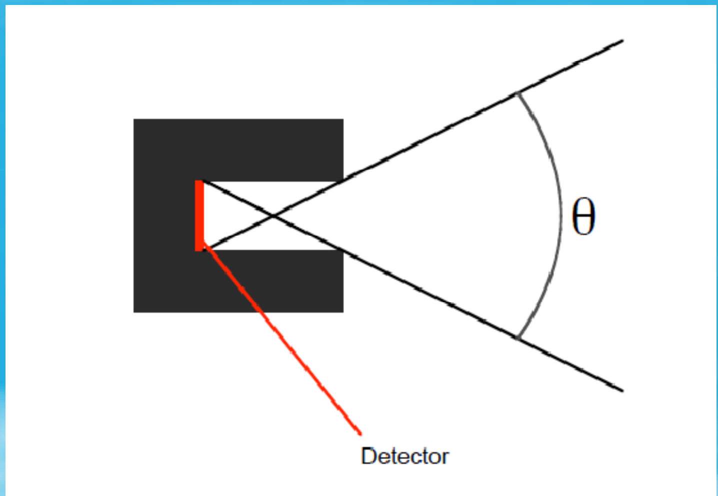
- Need transparent window
- Need absorptive gas

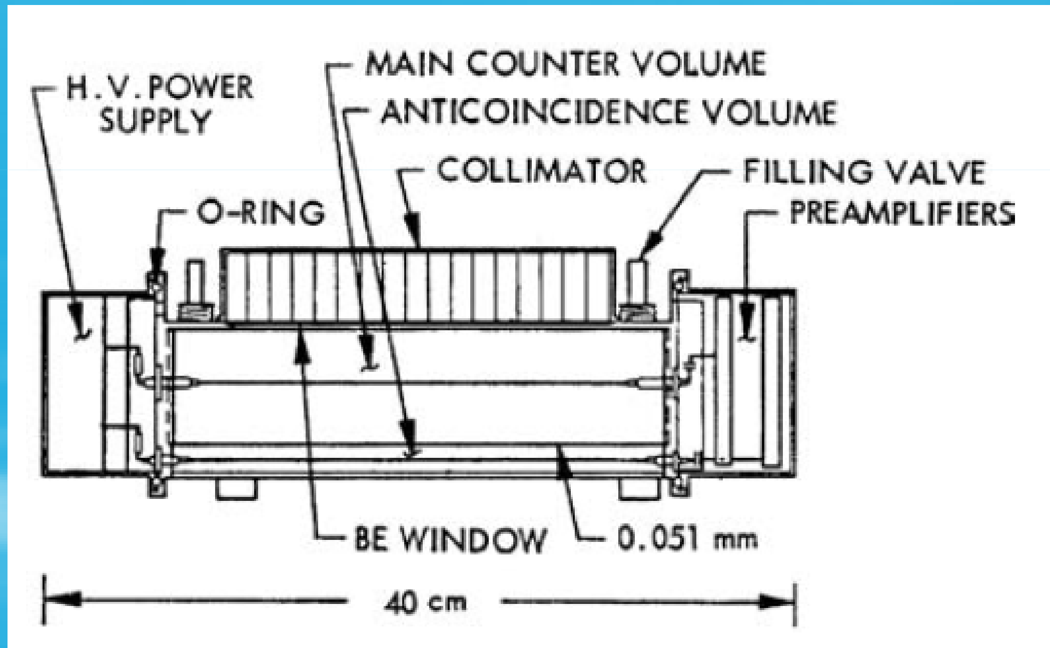




X-ray Source Location

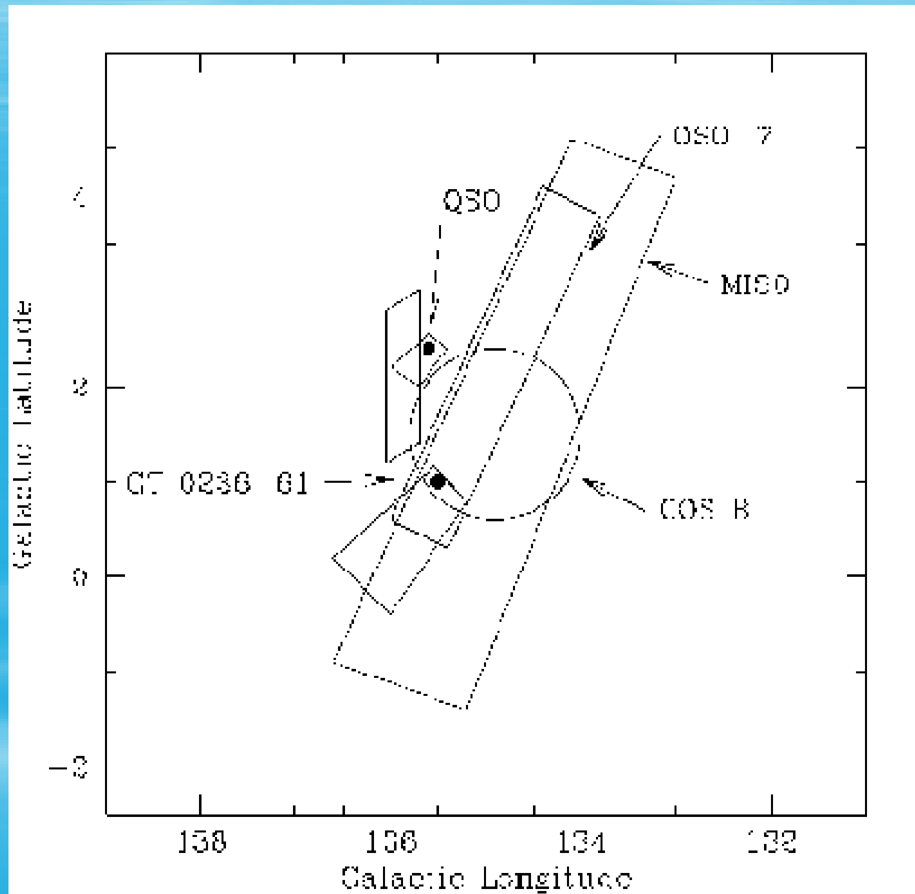
- Crude collimation by means of mechanical obstructions (slats or “egg crate” collimators)





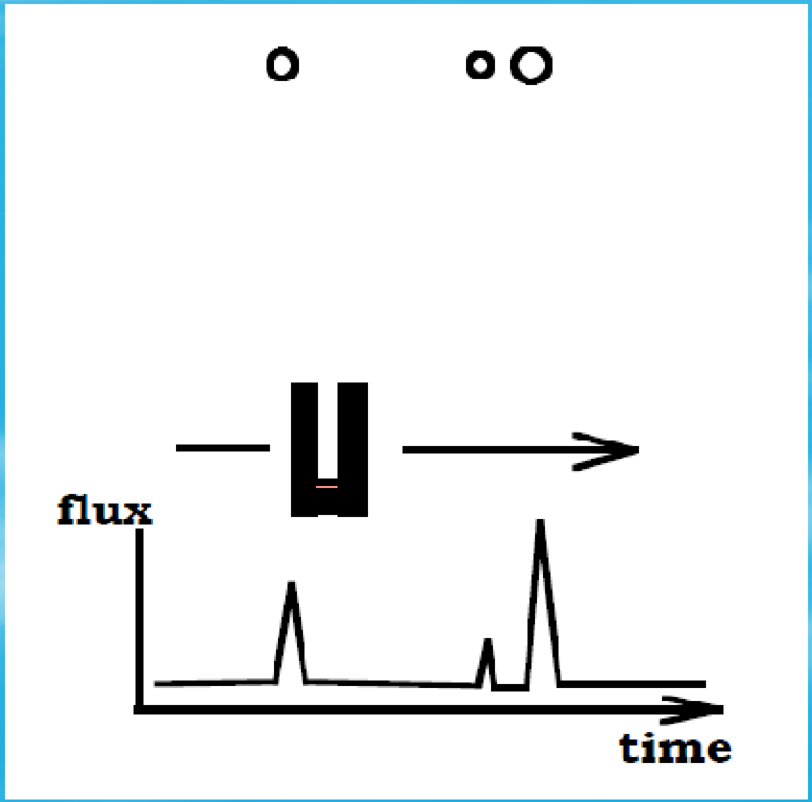
X-ray Source Location

- Non-imaging proportional counter only gave crude source postions
- Source confusion issues



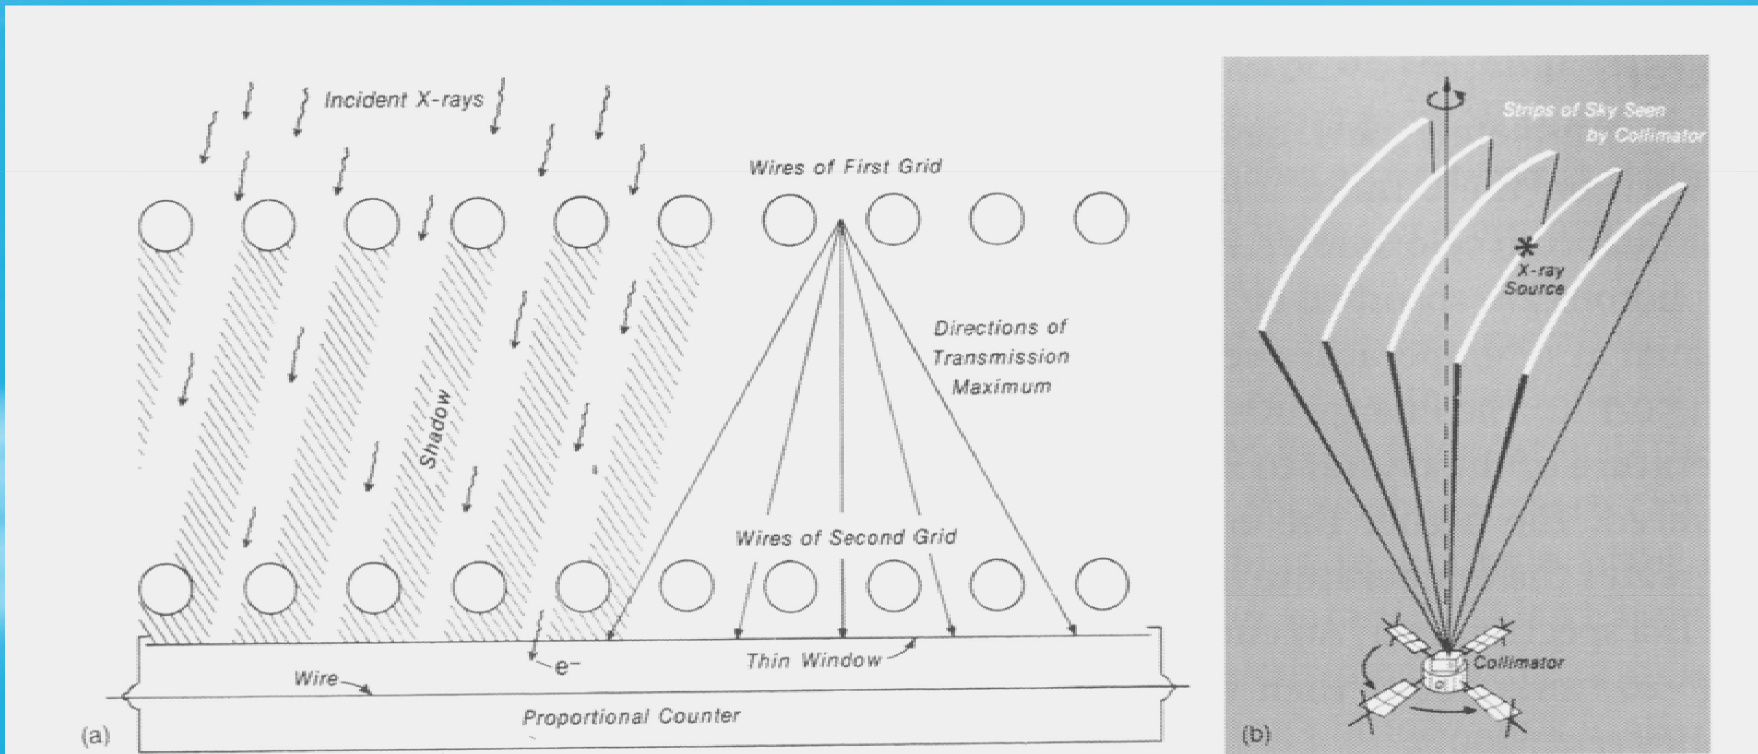
X-ray Source Location

- Improvements from using *modulation* collimators
- Rotate the satellite and periodically occult the X-ray source



X-ray Source Location

- *Scanning Modulation Collimator*
- *Rotating Modulation Collimator*

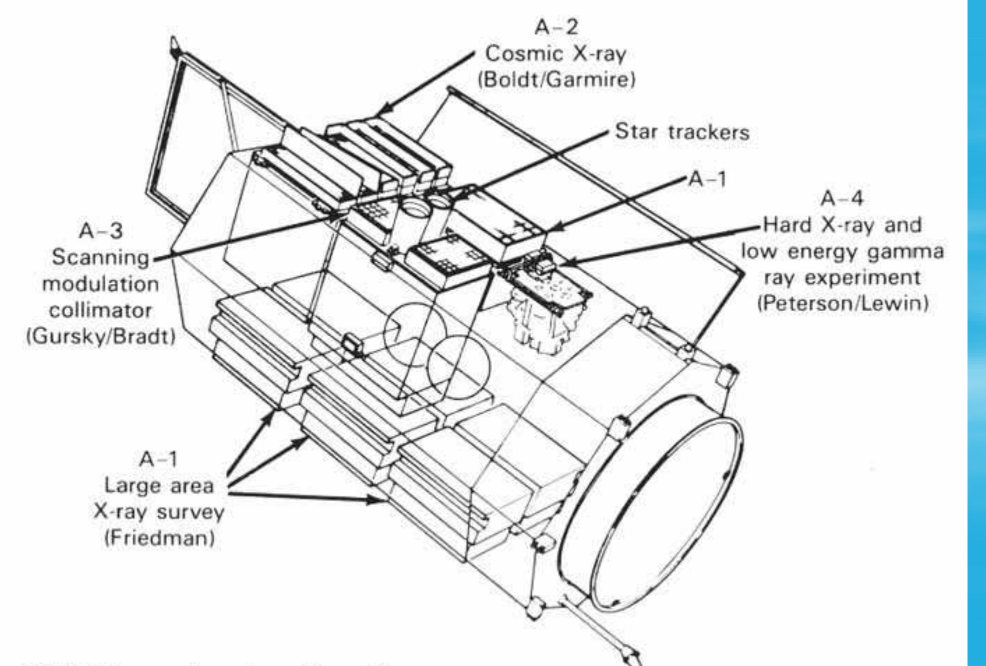


The First X-ray Astronomy Satellites

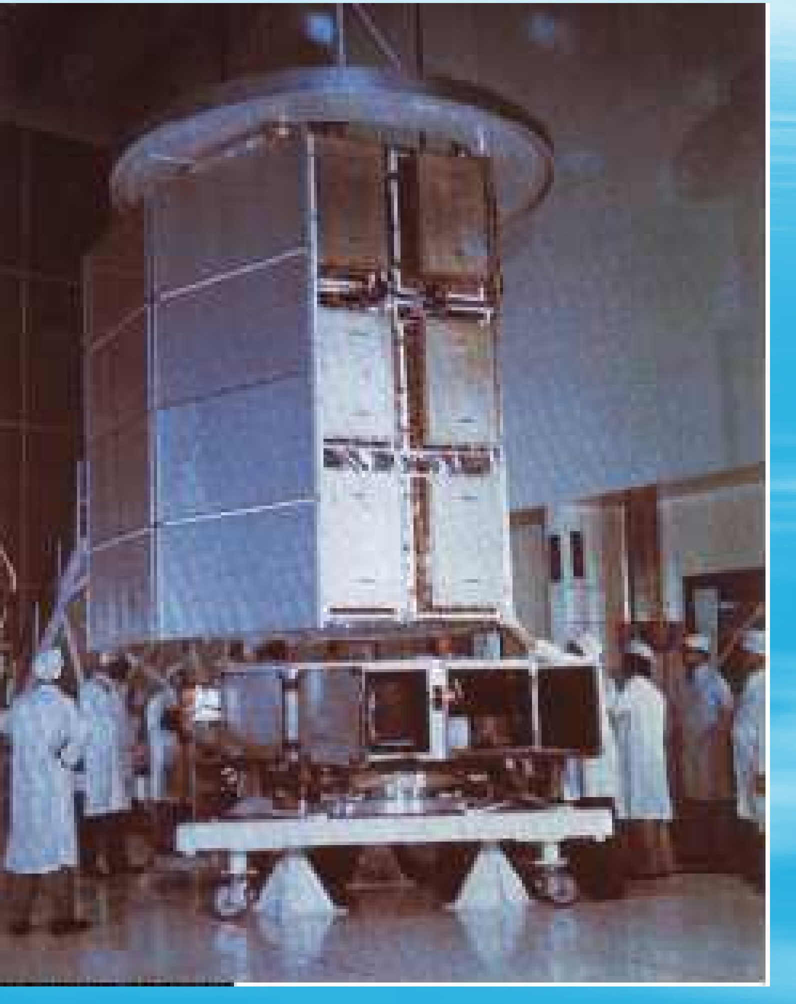
- **A number of smaller X-ray satellite missions (Ariel, SAS, OAO)**
- **All using PCs, some with modulation collimators**
- **Culminating eventually in the NASA *High Energy Astronomy Observatory* missions:**
  - **HEAO-1 (scanning collimation; first hard X-ray all-sky survey**
  - **HEAO-2 (renamed *Einstein Observatory;* first imaging X-ray telescope)**
  - **HEAO-3 (cosmic rays)**

HEAO-1

- **4 different instruments**
  - A1: hard X-ray large area PCs
  - A2: soft X-ray PCs
  - A3: hard X-ray scanning PCs
  - A4: gamma ray detectors

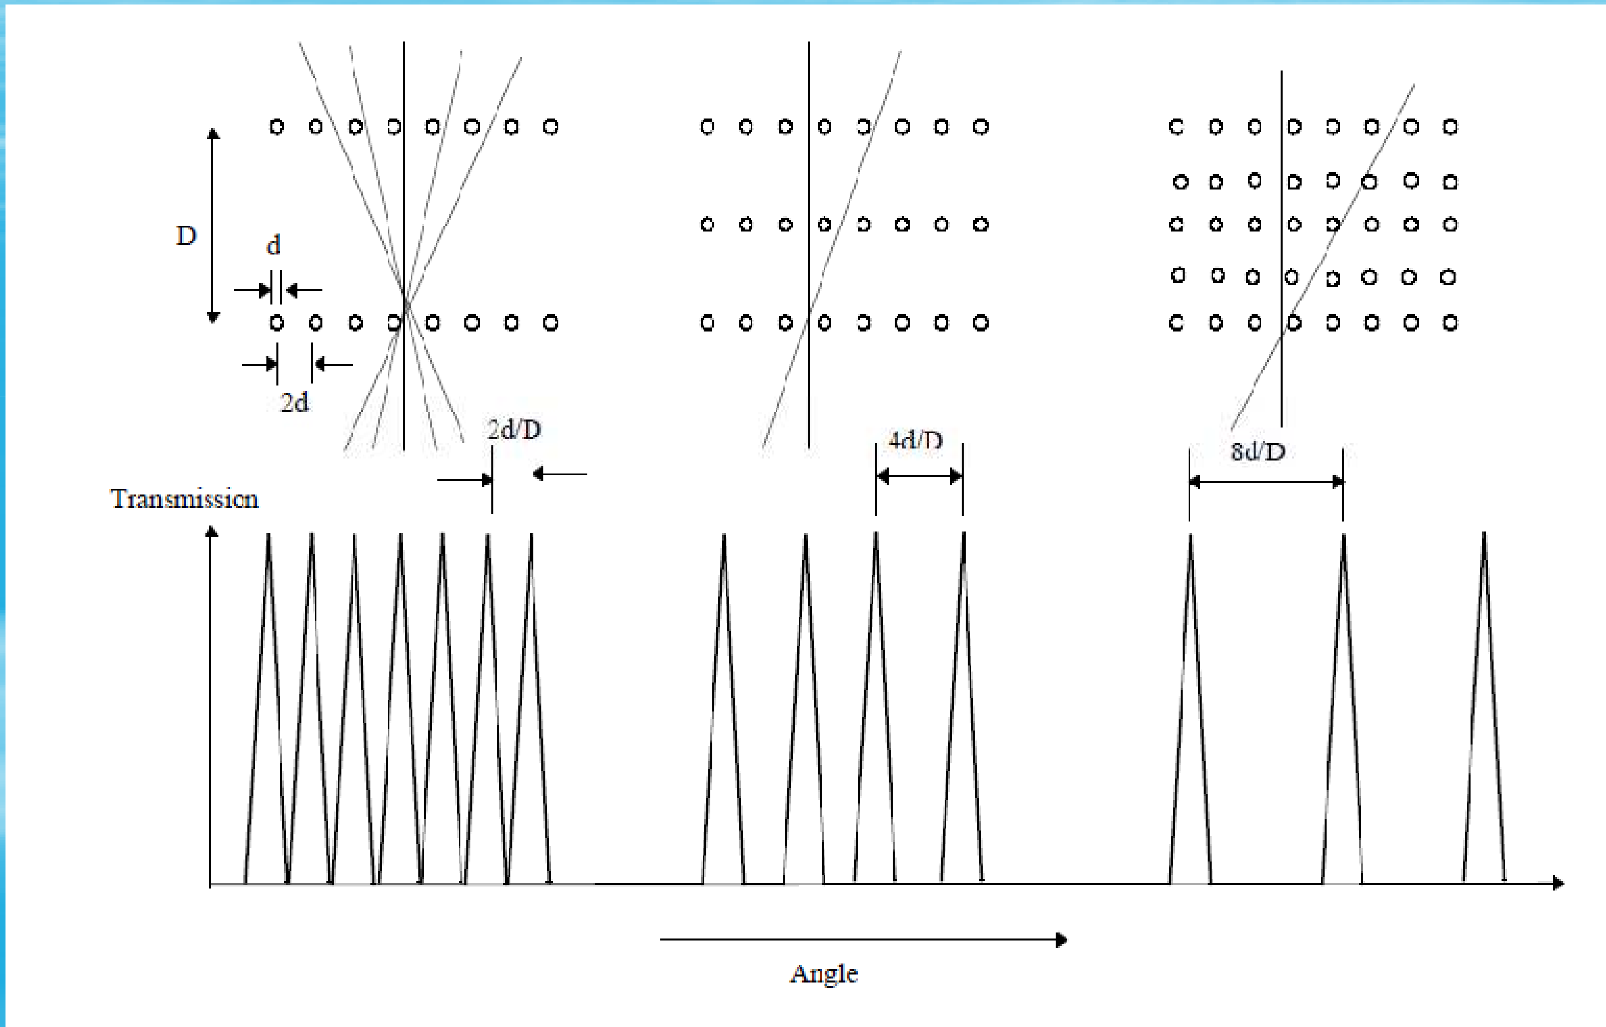


HEAO 1 experiment configuration.



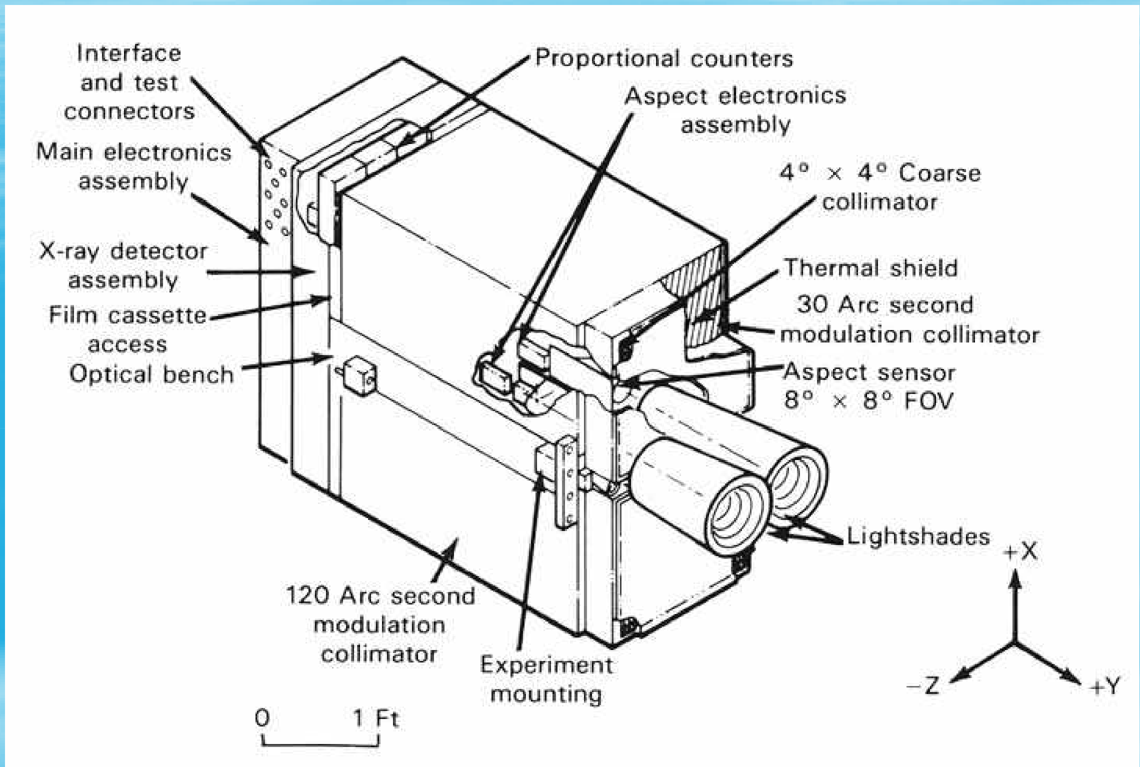
HEAO-1

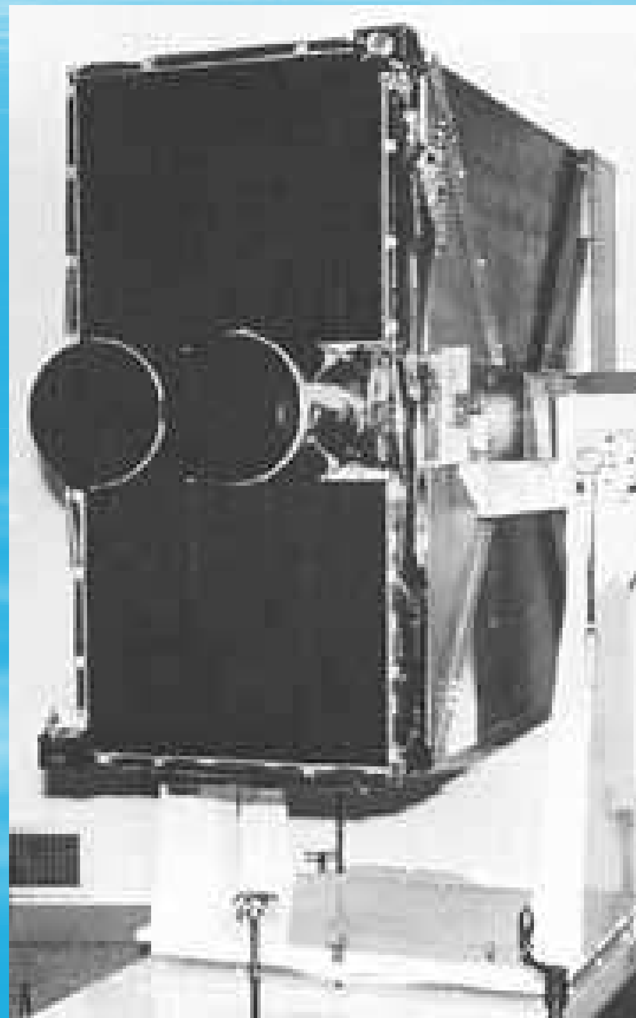
- *Scanning Modulation Collimator (A3)*



HEAO-1

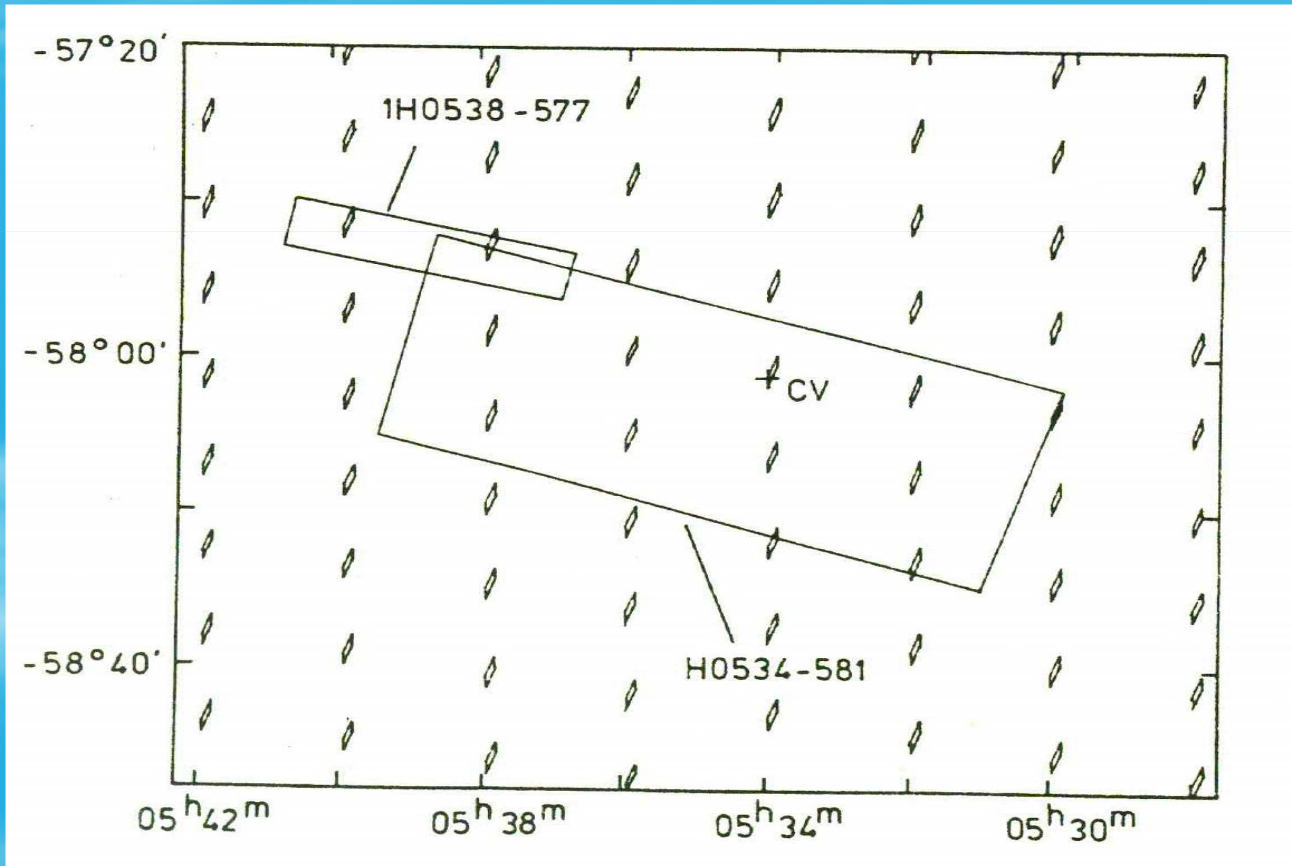
- *Scanning Modulation Collimator (A3)*





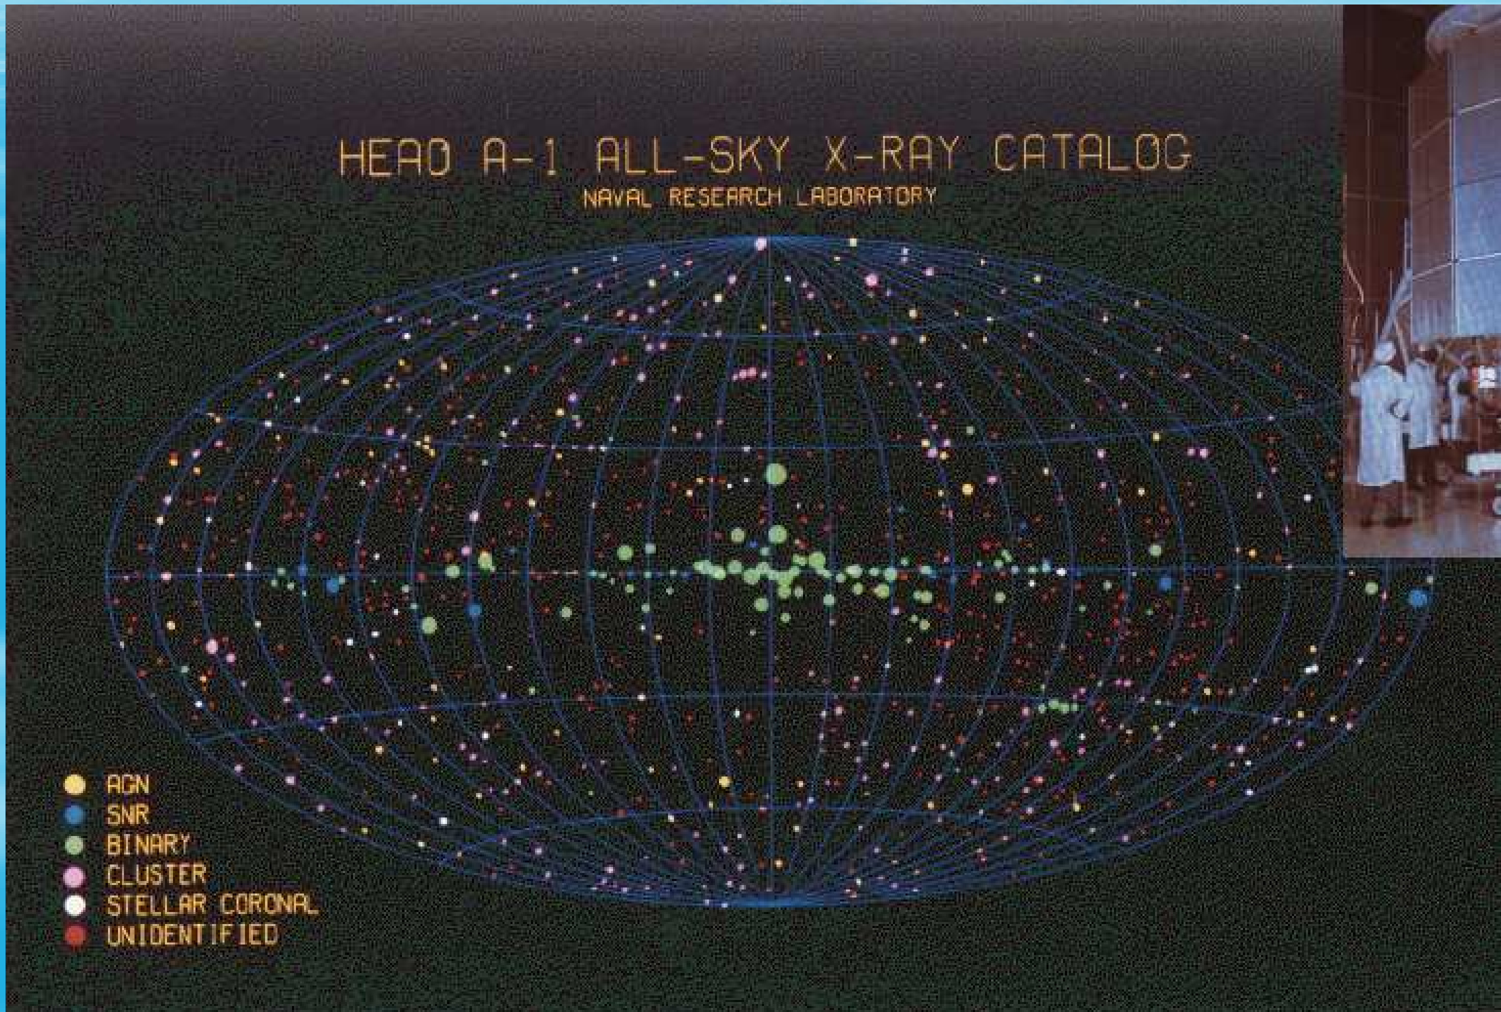
HEAO-1

- *Produced a regular grid of possible non-unique error boxes*
- *~1 x 2 arcmin over 4 x 4 degrees*
- *Any one of them could contain the source*



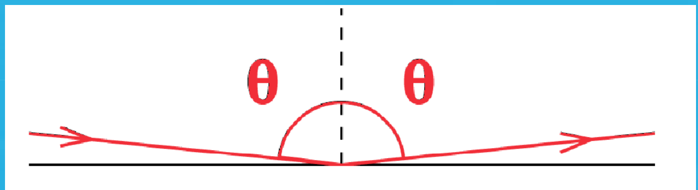
HEAO-1

- *Total of ~1000 sources detected*



First X-ray Telescope:
Einstein Observatory (HEAO-2)

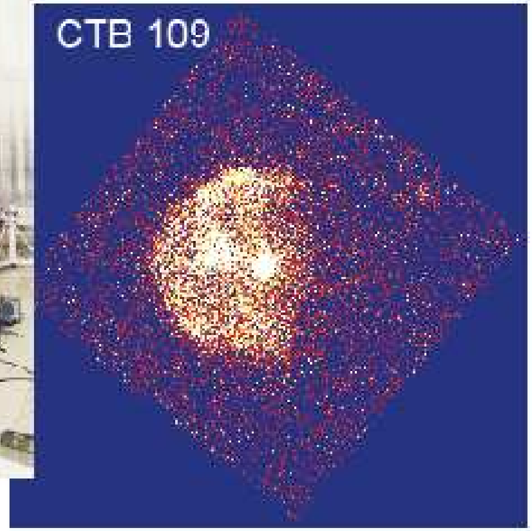
- First use of mirrors to focus X-ray
- Grazing incidence optics



- Pointed observations rather than all-sky survey
- Softer energies

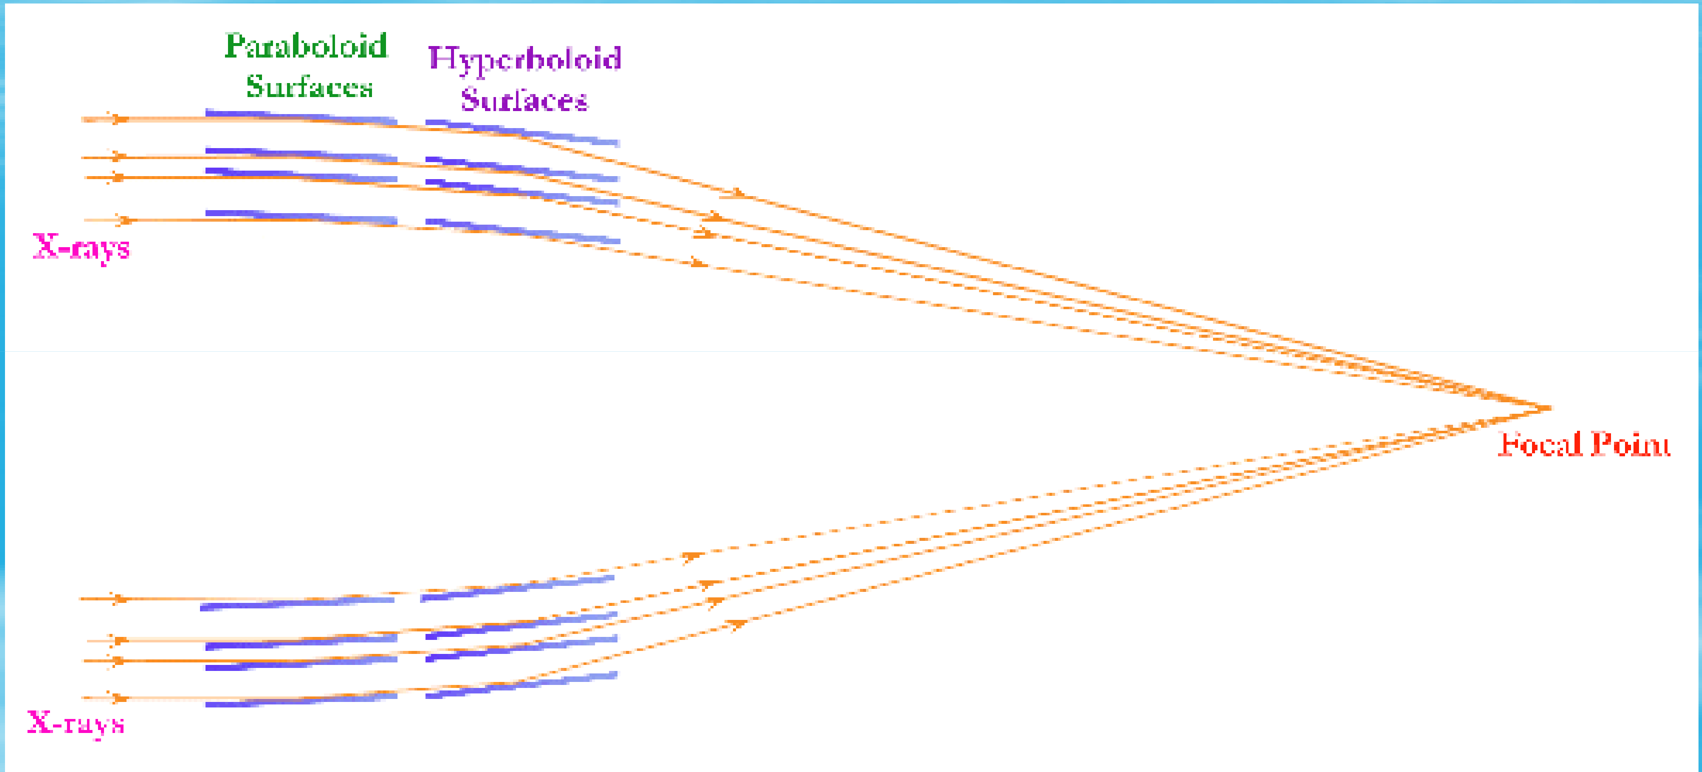
first imaging at 2-20 keV
several instruments (5-200 cm^2)

1000s of X-ray sources, discovery of jets (M87), spectroscopy



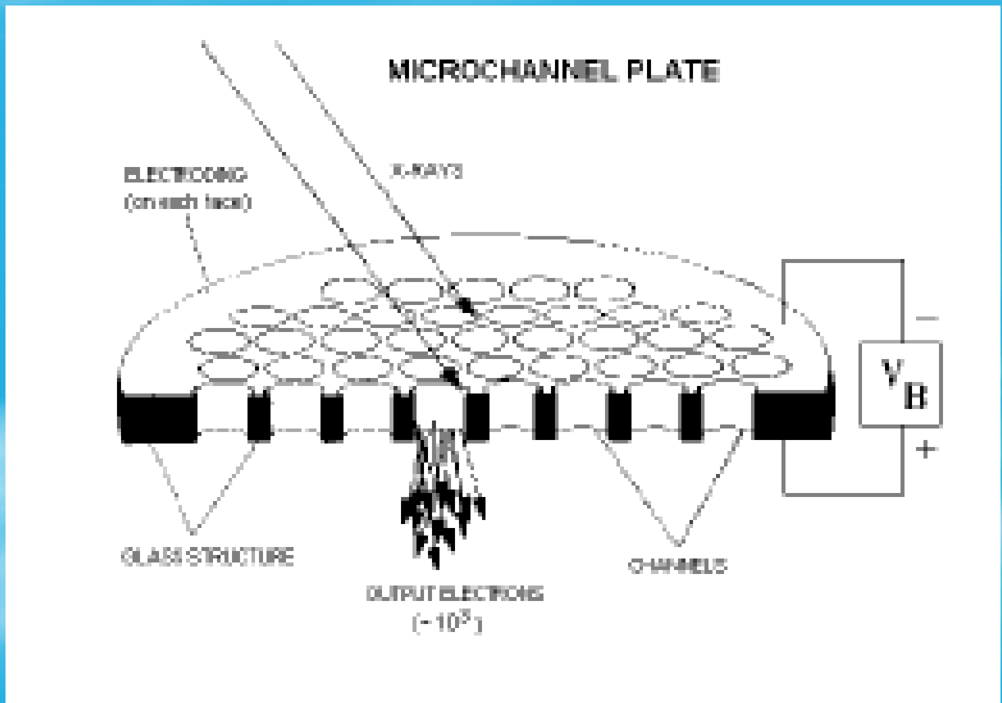
Einstein Observatory

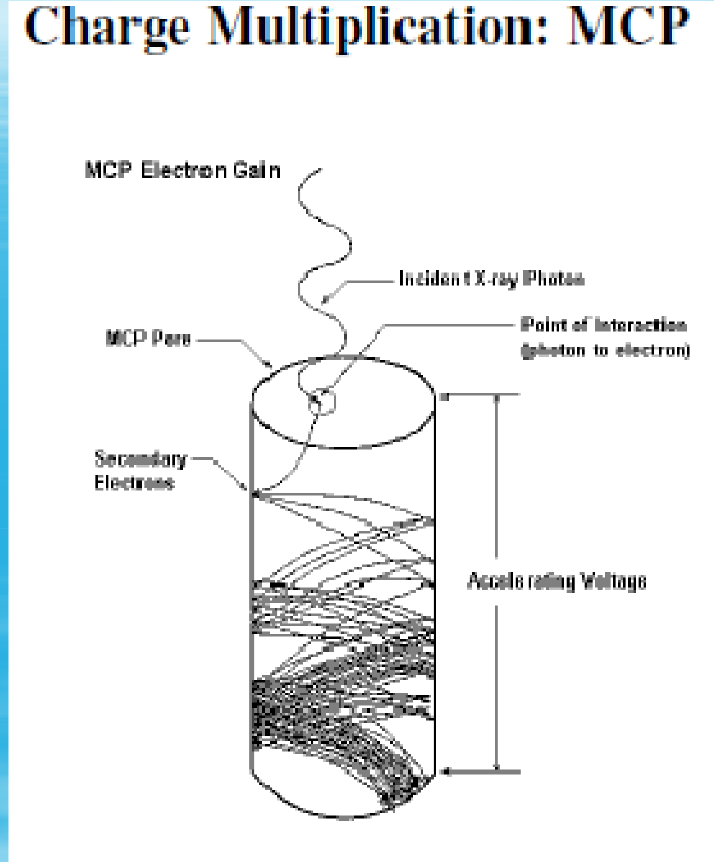
- The telescope design:



Einstein Observatory

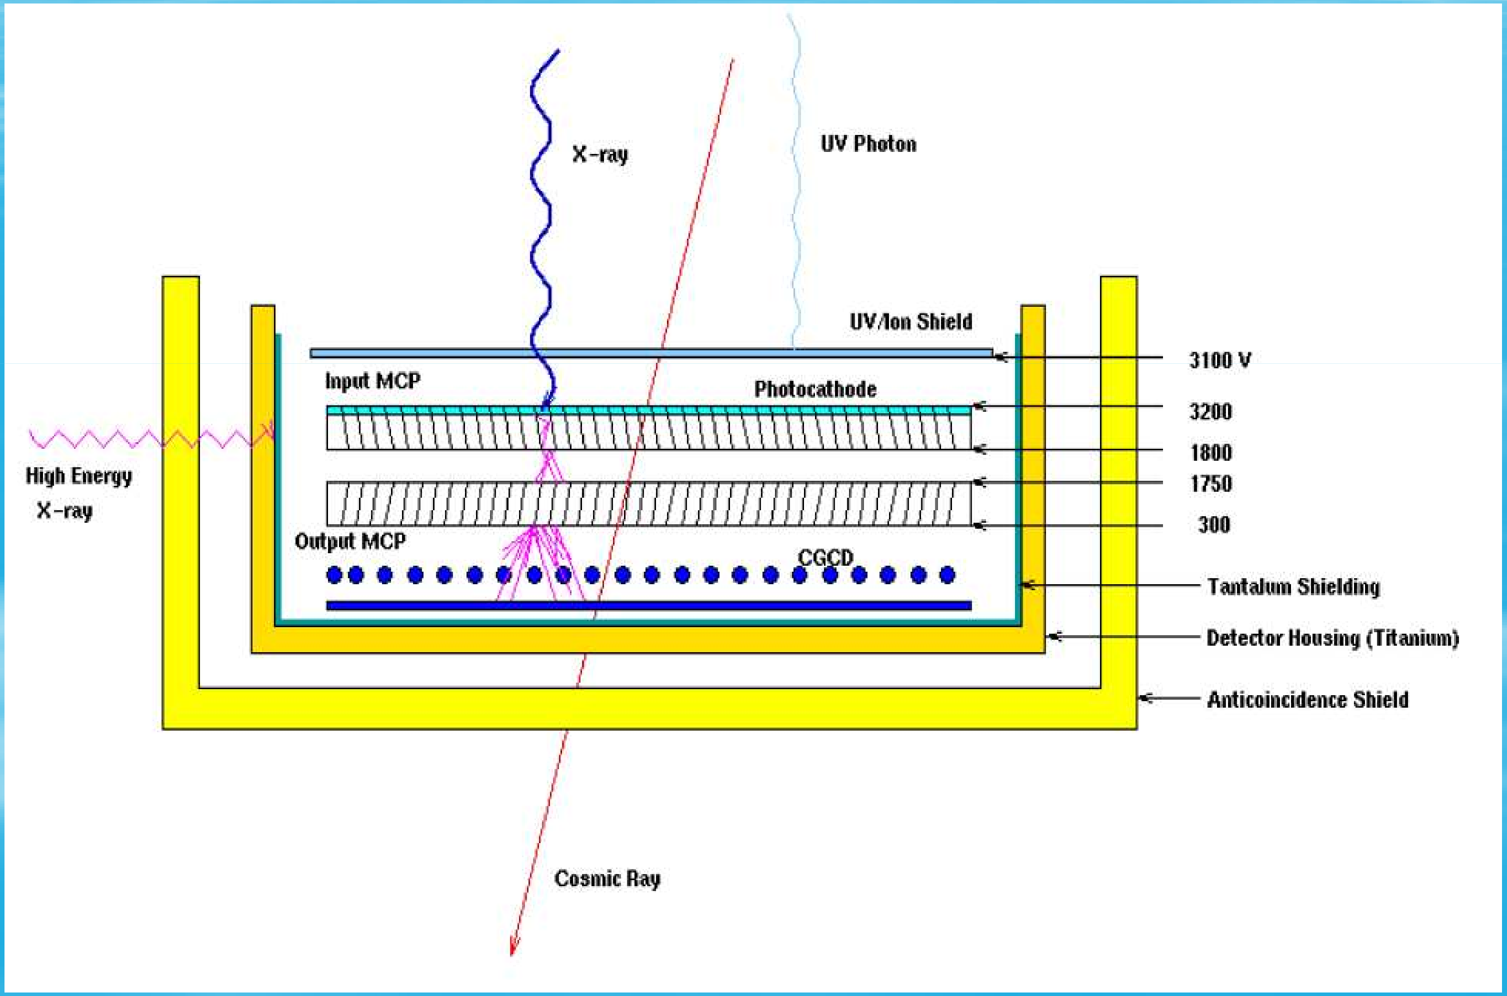
- New types of detectors
  - Micro-Channel Plate
  - Solid State Spectrometer





Einstein Observatory

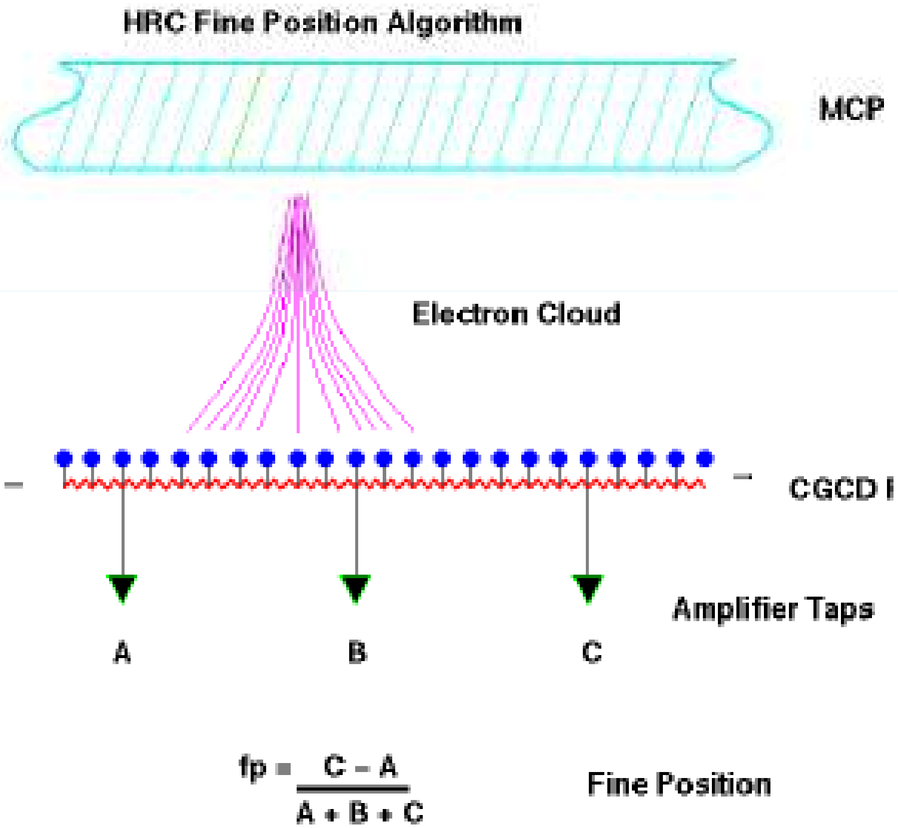
- New types of detectors
  - Micro-Channel Plate

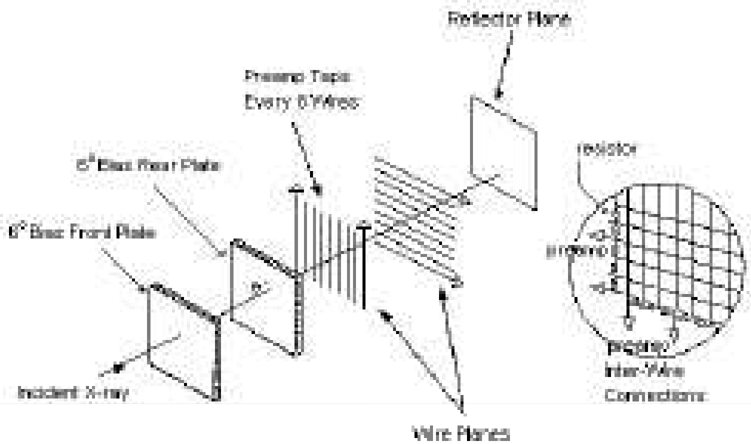


Einstein Observatory

- Micro-Channel Plates (MCP)

Position Readout: MCP



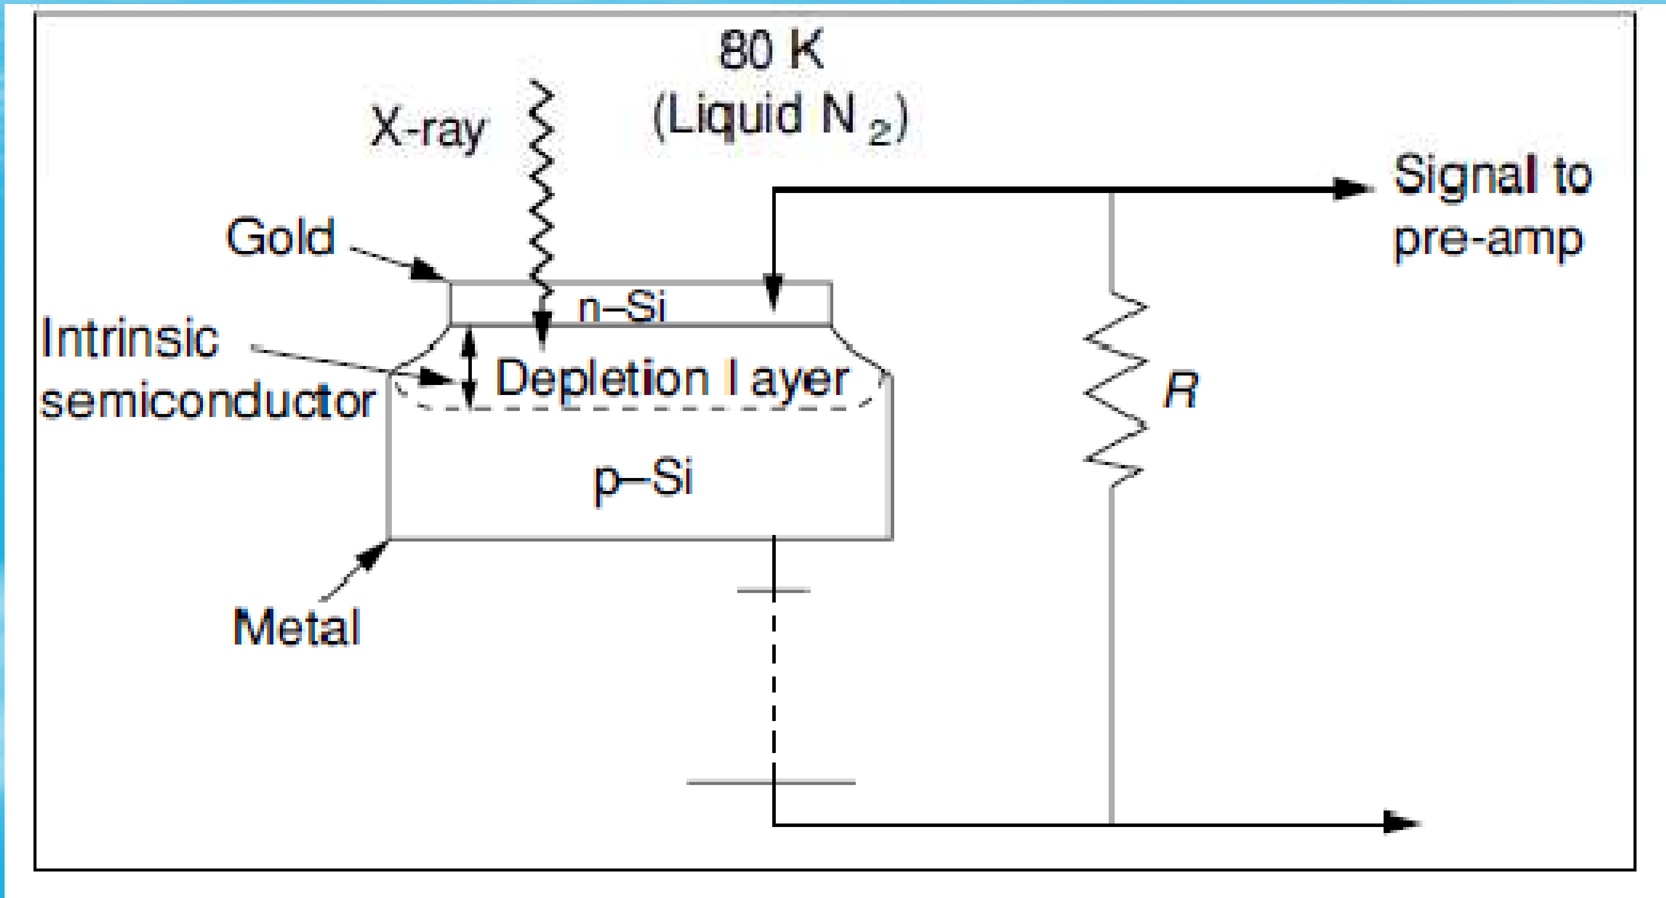


Position algorithm necessarily leaves "gaps"

Has non-linearities

Einstein Observatory

- New types of detectors
  - Solid State Spectrometer (CCD principle)



ROSAT: The next imaging X-ray satellite (1990)

- German-UK-US collaboration
- Soft X-ray survey (0.2 – 2.5KeV)
- Greatly improved sensitivity
- ~80,000 sources

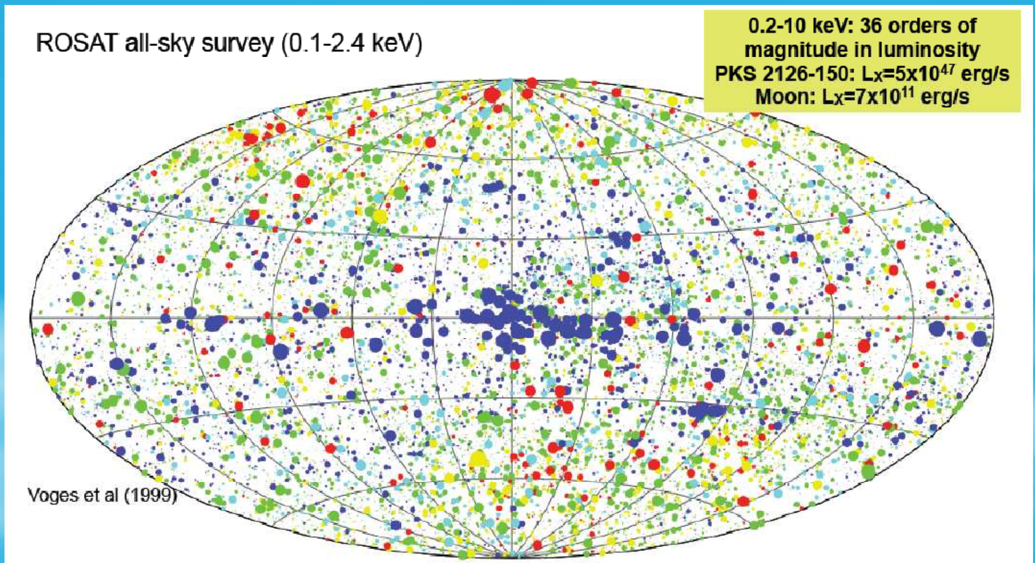


Fig. 5. Aitoff projection of the distribution of all RBSC sources obtained in the ROSAT All-Sky Survey observations until August 13, 1991 in galactic coordinates. The size of the symbols scales with the logarithm of the count-rate and the colours represent 5 intervals of the hardness ratio HR1: red ($-1 \leq$ HR1 < -0.6); yellow ($-0.6 \leq$ HR1 < -0.2); green ($-0.2 \leq$ HR1 $<$ 0.2); blue (0.2 $\leq$ HR1 $<$ 0.6) and violet (0.6 $\leq$ HR1 $\leq$ 1.0).

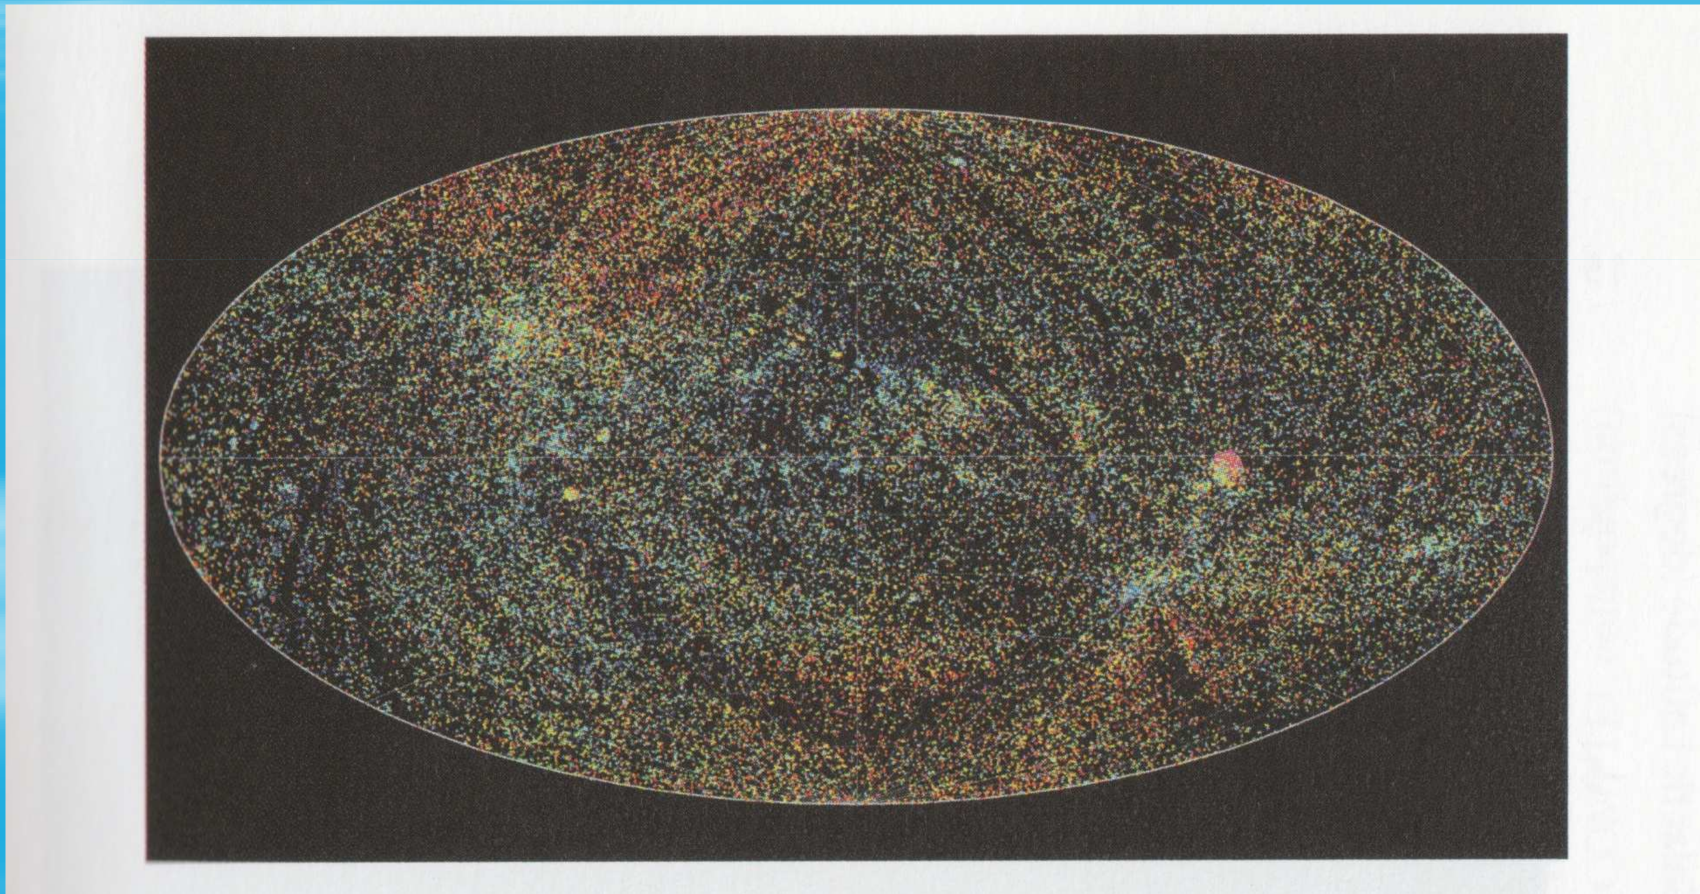
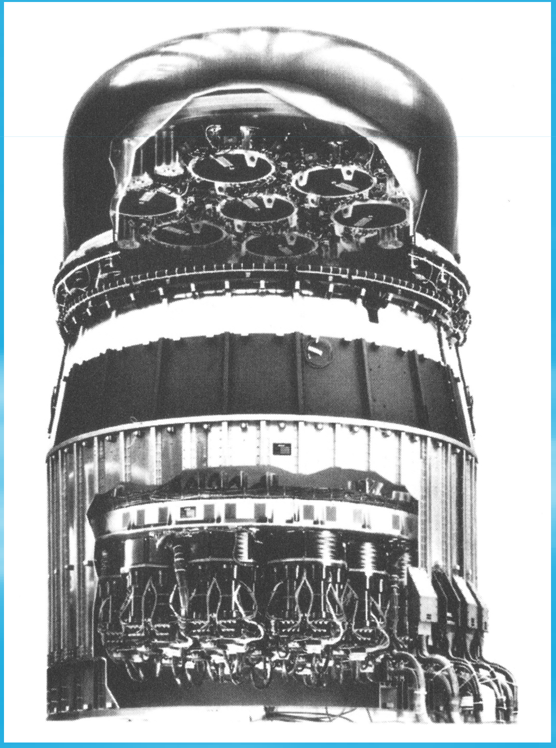
ROSAT

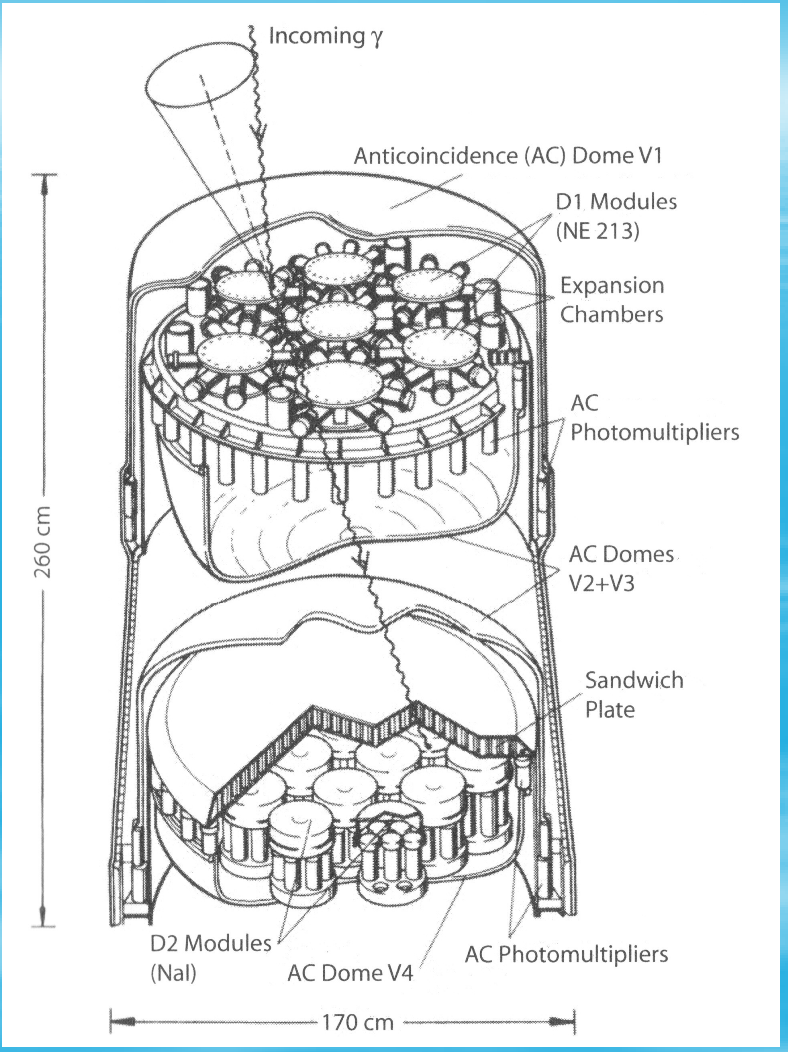
- Greatly improved sensitivity
- Also did first Extreme UV (EUV) survey
- Lots of source IDs and optical follow-up done at SAAO



Higher Energy Missions

- Gamma Ray satellites
- More energetic photons
- Can't "focus"
- Clever techniques to derive source positions (e.g. partical & nuclear physics
- Coded aperture masks (INTEGRAL)

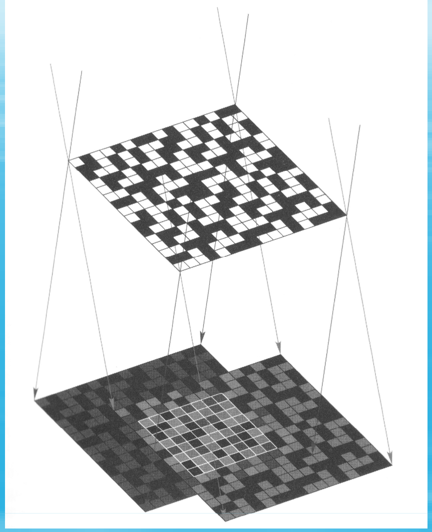


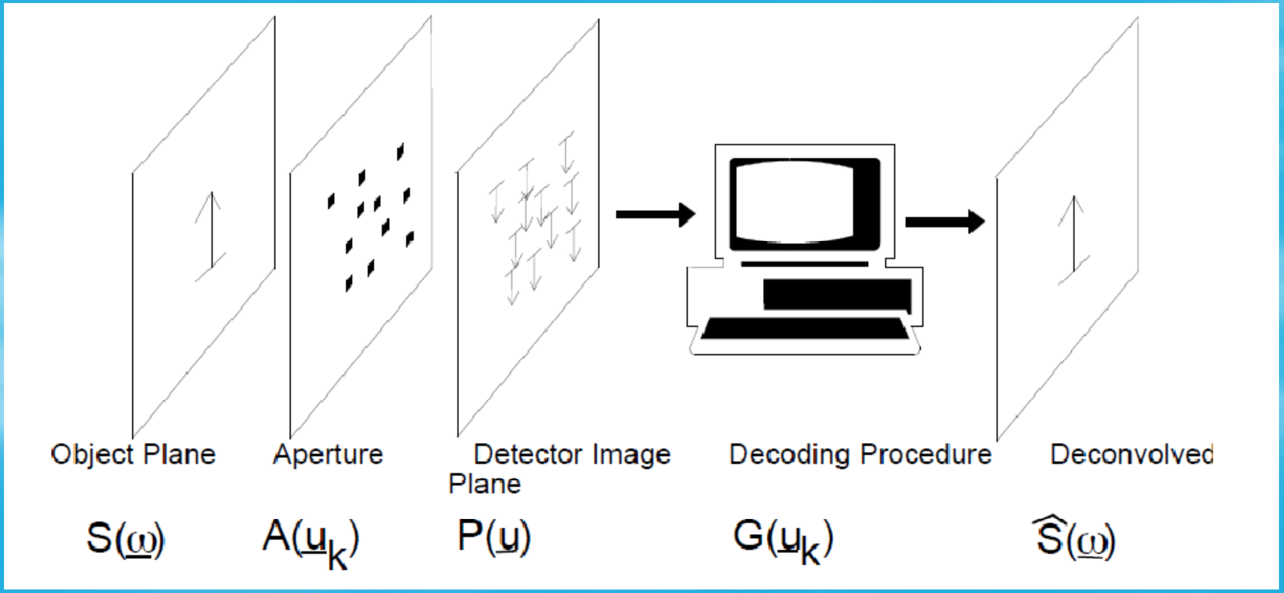


The *Compton Gamma Ray Observatory (CGRO)* was the first big NASA mission

Coded Aperture Masks

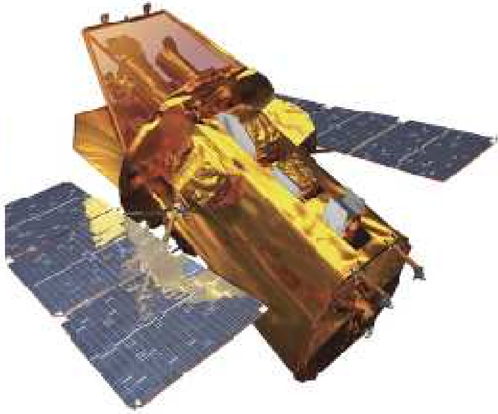
- Block out photons
- Look at shadow patterns
- Remove source confusion
- Locate to ~degrees
- Deconvolve multiple source positions





New Missions of the Millenia

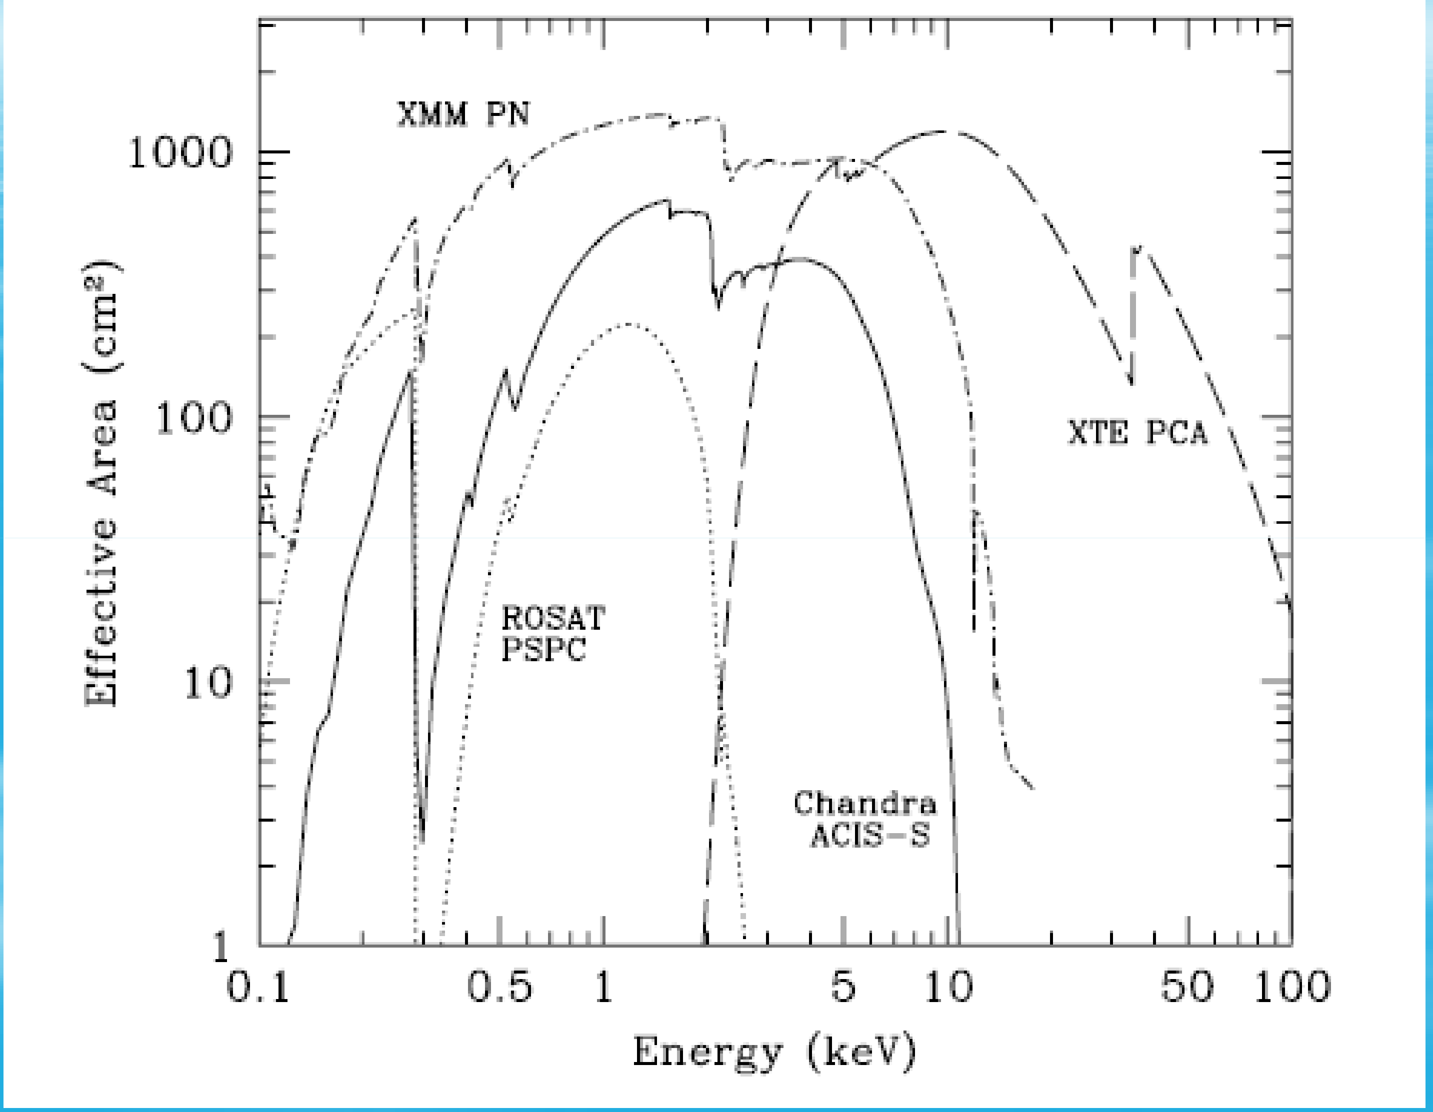
X-ray Astronomy today - Golden Age



New Millennium

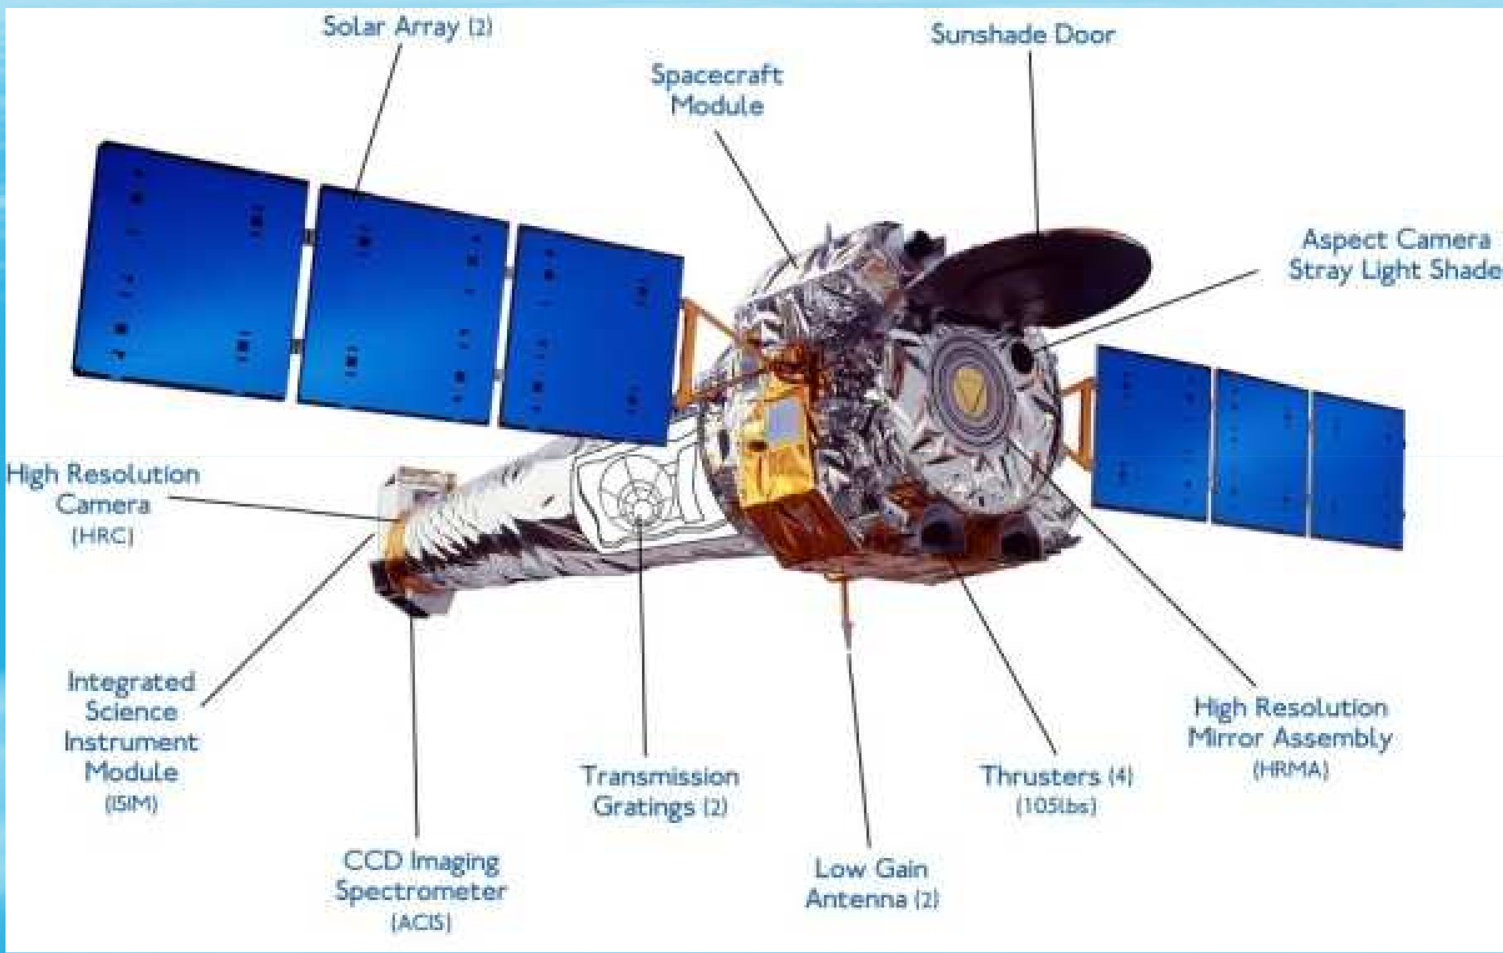
- 1999 saw launch of Chandra and XMM-Newton
  - NASA's Chandra high spatial resolution
  - ESA's XMM high sensitivity
- 2005: Japan's Suzaku mission launched
  - High resolution X-ray spectrometer failed after launch, imager still performing useful science

Improved Collecting Area



Chandra

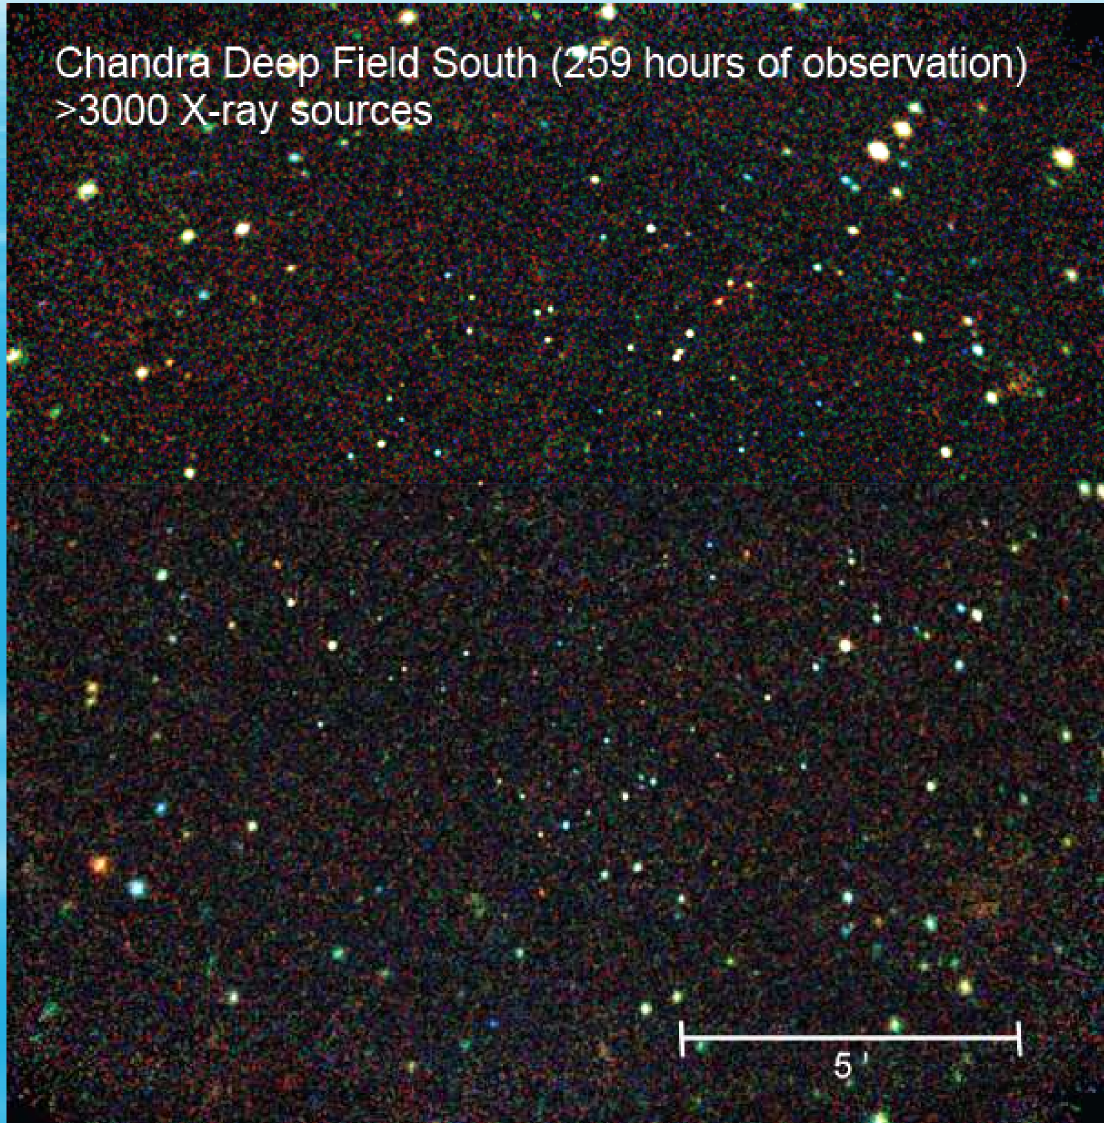
Chandra



Solar Array (2)
Sunshade Door
Spacecraft Module
Aspect Camera Stray Light Shade
High Resolution Camera (HRC)
Integrated Science Instrument Module (ISIM)
CCD Imaging Spectrometer (ACIS)
Transmission Gratings (2)
Low Gain Antenna (2)
Thrusters (4) (105lbs)
High Resolution Mirror Assembly (HRMA)

Chandra Results:

best resolution images to date

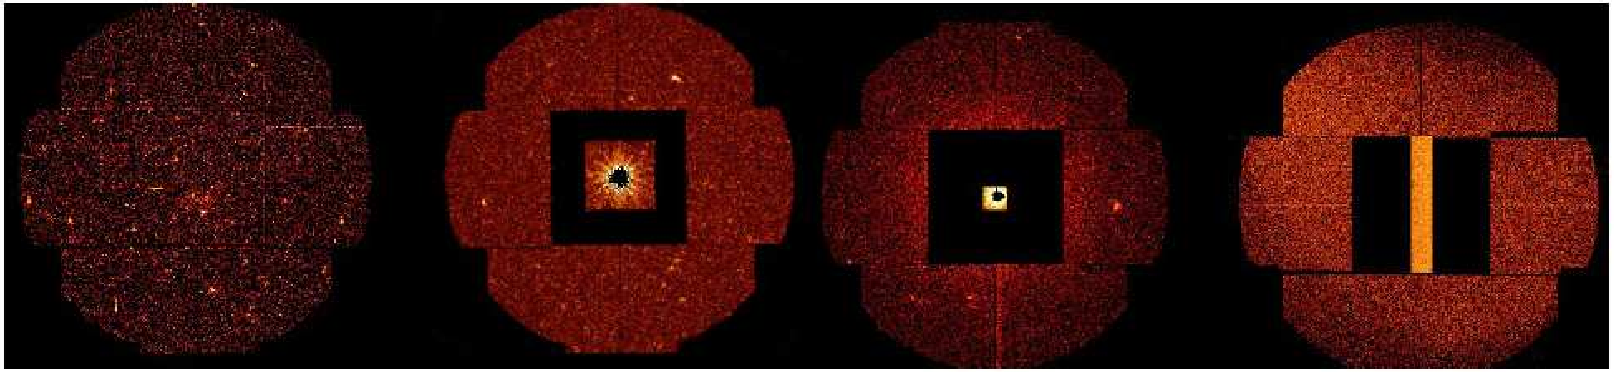


X-ray CCDs

- Energy of single X-ray sufficient to release many electrons in pixel
- Charge on a pixel when read out gives energy of photon
  - Providing only one photon detected by pixel
- Even brightest X-ray sources emit few photons per unit time compared to optical sources
- In a short exposure (~1s), each CCD pixel receives 0 or maybe 1 photon
- Long exposure built up from many short exposures and readouts
- Record position, energy and time of each photon

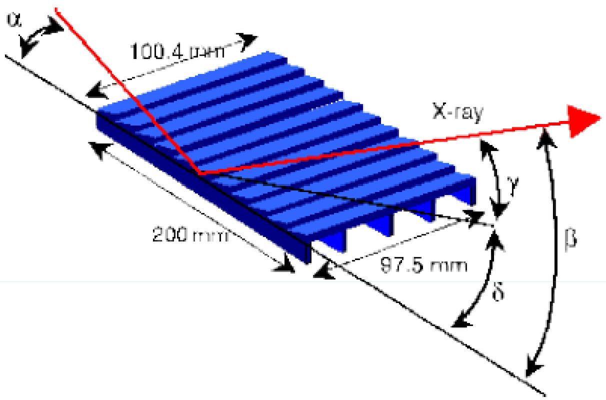
Time Resolution

- Time of arrival of photon determined from which short exposure & readout it was detected in
- The time taken to shuffle the charges between pixels to read out CCD places limit on time resolution
- Improve by only activating small part of CCD
  - reduces readout time
  - e.g. different timing modes of EPIC MOS camera on XMM-Newton

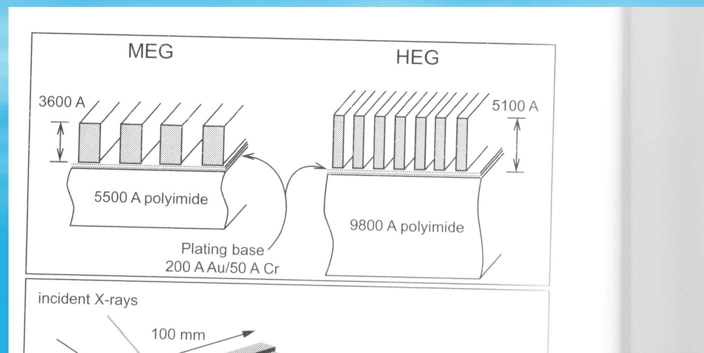


X-ray Gratings

- While CCDs provide good energy resolution, high energy resolution requires grating spectrometers
- Transmission or reflection gratings diffract X-rays

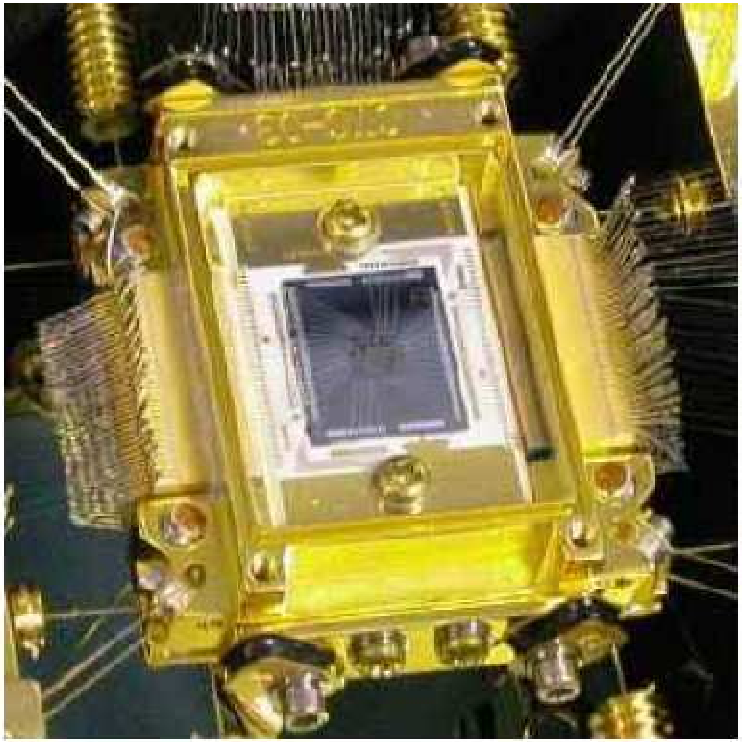


- Reflection gratings on XMM have ~650 lines/mm



X-ray Calorimeter

- First space-based calorimeter on Suzaku failed, but a calorimeter will be flown in the (near?!) future
- Detects the change in temperature due to the arrival of a single X-ray photon
- Uses Transition-Edge Sensors
  - resistance changes rapidly near critical temperature at which pixel becomes superconductor
- Excellent energy resolution
  - few eV or better



Current X-ray Missions

Key Points

- X-ray telescopes use grazing reflections
- Most modern detectors are arrays of CCDs
- Energy of X-ray determines charge released in pixel
- Use grating spectrometers for higher energy resolution
- Record position, energy, time of each photon
