

Preliminary alternate recovery target results for alternate future poaching scenarios based on different tunings of the current OMP

S.J. Johnston and D.S. Butterworth

Results presented here incorporate the new poaching scenarios (both historic and future) that were recently recommended by the SWG.

The two scenarios relating to past/historic poaching with the SWG-agreed relative weightings are:

Poaching historic=500 MT with WT=0.65
Poaching historic=250 MT with WT=0.35.

Along with three scenarios for future recruitment, two scenarios for future somatic growth, and three scenarios for alternative current abundance, a total of 36 total scenarios are now defined – each with an associated total weighting which depends on the individual weights of the various factors. Table 1 reports these 36 scenarios in more detail.

Two preliminary future options relating to future poaching levels were identified:

Option A: 2009 poaching = +12%
 2010+ poaching = +25%

Option B: 2009 poaching = +50%
 2010+ poaching = +100%

No weighting between these two options has yet been decided (and the options themselves may change given further analyses) and results are presented in this document separately for each option to illustrate the differences more clearly.

Future poaching splits are as agreed by the SWG at its last meeting, these being:

A12: 0.15%
A34: 24.97%
A56: 30.13%
A7: 10.0%
A8: 34.75%

Recreational future take splits between super-area: the table below show the proportional splits used in current OMP and those recently estimated by the 2010/11 telephone survey.

	Current assumptions	2010/11 telephone survey
Area 1+2	2%	4.7%
Area 3+4	12.5%	9.9%
Area 5+6	12.5%	14.0%
Area 7	4%	8.4%
Area 8+	69%	63.1%

Results presented here assume the current assumptions continue to apply as these are not much different from the 2010/11 telephone survey results.

The aim of this document is to show the sensitivity of short-to-medium term future catches to alternate recovery targets, and how this depends on Option A vs Option B future poaching scenarios.

The results presented here are produced using the “Current” sector splits as defined in Table 2. Two different tunings are presented (note that the 4560 tuning is the current OMP 2007 re-cast tuning parameter).

Results

For all cases 700 simulations were run. Table 3a reports comparative results between the Option A and Option B future poaching scenarios for $\alpha=4560$. Table 3b reports comparative results for the Option B future poaching scenario for two alternate tunings ($\alpha=4560$ and $\alpha=3200$).

Figure 1 shows the total absolute median $B75m$ trajectories, the median $B75m$ relative to the 2006 values, and the median commercial TAC trajectories comparing Option A vs Option B future poaching scenarios for the current tuning of $\alpha=4560$.

Figure 2 compares results of two alternate tunings ($\alpha=4560$ and $\alpha=3200$) for the future poaching Option B.

Table 1: The 2011 OMP simulation scenarios.
